Abstract: The present paper Studies of Metal Complexes as Ligands: Trinuclear Alkali Metal Complexes with Copper(II) Acetylacetonate.

A report on prepration and characterization of some new complexes of the genral formula $[Cu(ac-ac)_2(ML)_2,$ has been presented here

M= Li, Na or K

L= Deportonated picolinic acid, salicylic acid, acetyl acetone, 0- nitrobenzonic acid

Acac= Acetylacetone

The paper also study the Magnetic measurements were taken on cation Faraday electronic balance at 27°C. The magnetic moment of Cu(acac)₂ is 2.1 (B.M.) and suggested a square planer structure, while the magnetic moments of adducts are also in between 2.1 to 2.3 B.M.

Keywords: Alkali metal, Ligand, Copper(II), Acetyl acetone, etc.

I. INTRODUCTION

The study of the coordination chemistry of alkali metal is interesting due to its possible role in plant metabolism, desalination of sea water and to understand its transport mechanism from soil to plant. This wonderful field remained unexplored and neglected till recently. Because of the nature of alkali metal complexes no d-d transition, no magnetic properties, instability to solution, very little work has been done either to investigate the few known compounds or to prepare new ones. However, the work has been extended to use transition metal complexes as ligand, in which magnetic property and absorption spectra have been considered to justify the alkali metal complexes.

The formation of oxygen bridged binuclear complexes from copper salicylaldimine has been well established by previous workers. In view of the above information, it was decided to extend the investigation by a synthetic application of the complexes of Cu(acac)₂ with alkali metal salts.

The complexes of alkali metals known so far are usually decomposed by water. Therefore, most of the work has been carried out in non-aqueous solvents.

II. EXPERIMENT

The formation of Cu(acac)₂ has well been established.¹⁻³ Our usual method of synthesis was to take Cu(acac)₂ in a mixture of benzene and absolute ethanol and alkali metal salts were added to it in the ratio of 1:2. It was refluxed with constant stirring in hot plate for about 1-2 h. Finally, the adducts were precipitated in hot condition.

The results of elemental and physical data of the complexes are given in Table 1.

TABLE 1

Compound	Colour	Analysis % : Found/ Calcd				Decomp.	μeff
		C	H	N	Cu	Temp (⁰ C)	(BM)
Cu(acac) ₂	Blue	-	-	-	-	240	2.1
Cu(acac) ₂	Brownish	51.21	4.56	5.62	12.12	265	2.2
(Li PreA) ₂	Yellow	(50.81)	(4.29)	(5.38)	(12.12)		
Cu(acac) ₂	Brown	47.38	4.21	5.22	11.23	260	2.2
(Na PreA) ₂		(47.86)	(3.98)	(5.07)	(11.51)		
Cu(acac) ₂	Brown	45.35	3.89	4.69	10.23	263	2.1
(K PreA) ₂		(45.24)	(3.77)	(4.79)	(10.8)		
Cu(acac) ₂	Brown	47.43	3.88	4.72	10.30	217	2.3
(Li ONBA) ₂		(47.41)	(3.42)	(4.61)	(10.54)		
Cu(acac) ₂	Brown	45.06	3.68	4.36	9.32	265	2.1
(Na ONBA) ₂		(45.03)	(3.44)	(4.37)	(9.92)		
Cu(acac) ₂	Brown	42.92	3.26	4.28	9.42	213	2.2
(K ONBA) ₂		(42.88)	(3.27)	(4.16)	(9.45)

(Li SalA) ₂	Yellow	(52.41)	(4.36)		(11.55)		
Cu(acac) ₂	Brownish	49.51	4.68	_	10.86	262	2.2
(Na SalA) ₂	Yellow	(49.52)	(4.12)		(10.90)		
Cu(acac) ₂	Brown	46.82	4.11	- 0-4	10.21	264	2.1
(K SalA) ₂		(46.94)	(3.91)		(10.35)	P.	

III. RESULTS AND DISCUSSION

The high decomposition temperatures of these adducts, compared to that of Cu(acac)₂, show the strong bonding, probably through oxygen atoms of complex ligands to the alkali metals.

Magnetic measurements were taken on cation Faraday electronic balance at 27°C. The magnetic moment of Cu(acac)₂ is 2.1 (B.M.) and suggested a square planer structure, while the magnetic moments of adducts are also in between 2.1 to 2.3 B.M. Therefore, the stereochemistry of Cu(acac)₂ unit in alkali metal complex compounds almost remains same. Hence it suggests that alkali metals are coordinated through the oxygen atmos of the ligands [Cu(acac)₂].

The adducts are characterized by observing the C—O stretching frequency in IR spectra metal complex ligands and the alkali metal complexes.⁴⁻⁹

The Infrared spectra measurements were made in Nujol Mull for the ligands and complexed between $4000 - 650 \text{ cm}^{-1}$. Selected absorption band in different regions are given in table 2.

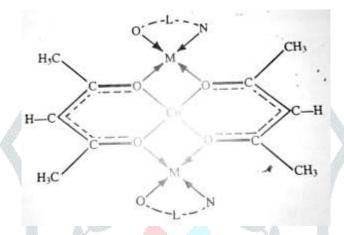

TABLE 2

Compounds	Frequency (cm ⁻¹)			
Cu(acac) ₂	1577	1552	1529	
Cu(acac) ₂ (Li PreA) ₂	1590	1505	1520	
Cu(acac) ₂ (Na PreA) ₂	1595	1540	1520	
Cu(acac) ₂ (K PreA) ₂	1590			
Cu(acac) ₂ (Li ONBA) ₂	1590			
Cu(acac) ₂ (Na ONBA) ₂	1590			
Cu(acac) ₂ (K ONBA) ₂	1595			
Cu(acac) ₂ (Li SalA) ₂	1592			
Cu(acac) ₂ (Na SalA) ₂	1590			
Cu(acac) ₂ (K SalA) ₂	1590			

It has been generalised that metal acetyl acetonates, when they are monomeric, the C=O frequency is below 1580 cm⁻¹ whereas ehen it is a polymer with oxygen bridging, the C—O frequenct splits into two, one above 1580 cm⁻¹ due to bridging and the other below 1580 cm⁻¹ (normal).

In these polynuclear alkali metal copper(II) acetyl acetonates, the C—O frequencies have been observed not to be in their normal range, but invariably higher between 1580-1600 cm⁻¹. This is quite suggestive that all these oxygen are bridged ones, bridging the copper metal and most probably the alkali metal¹⁰⁻¹⁴.

From magnetic properties and I.R. spectra of the adducts, it is clear that the bonding between $Cu(ac.ac)_2$ and alkali metal salts is most likely through oxygen atoms of carbonyl group. The structure and bonding of the newly prepared compounds corresponding to the general formula $[Cu(acac)_2(ML)_2]$ is shown in below structure.
