## Abstract

The topological groups are dealing with the continuity of the group operations. In this paper, we gave a survey report on the topological and semi-topological groups. Some results are also given with explanation.

**AMS Mathematics Subject Classification 2010:** Primary 40A05, Secondary 46A45

## 1. Introduction

**Definition 1.1: (Semi Topological Group)** A triple  $(G, \tau, *)$  is called as semi-topological group, where  $(G, \tau)$  is a topological space and  $(G, *)$  is a group, if the group operations  $*$  :  $G \times G \rightarrow G$  that maps  $(x, y)$  to  $x * y$  is continuous in each variable, i.e., the mapping  $g_{y_0} : G \rightarrow G$  by  $x \rightarrow x * y_0$  and  $g_{x_0} : G \rightarrow G$  by  $y \rightarrow x_0 * y$  are continuous for all  $y_0$  in  $G$  and  $x_0 \in G$ , respectively

**Remark 1.1:** A semi-topological group is a pair  $(G, *)$  with a topology  $\tau$  such that  $\forall x, y \in G$  and each open set  $W \ni x * y^{-1}$  there are open sets  $U \ni x$  and  $V \ni y$  such that  $U * V^{-1} \subset W$ .

**Example 1.1:** The  $(R, +, \tau_\ell)$ , where  $\tau_\ell$  is the lower limit topology,  $\tau_\ell = \{[a, b) : a, b \in R\}$  generated by a set  $[a, b) : a, b \in R$  and  $a < b$ . Here, the mapping  $(x, y) \rightarrow xy$  is a continuous, but  $x \rightarrow x^{-1}$  is not continuous.

**Remark 1.2:** For semi-topological and topological groups we have the following results:

- (a) When we take group operation addition instead of multiplication then we replace  $x.y$  by  $x + y$  and  $x^{-1}$  by  $-x$ .
- (b) Clearly by definition, every topological group is a semi topological, but converse is not true, in general.

**Theorem 1.1:** Let  $X$  and  $Y$  be two spaces. Suppose that  $f : X \rightarrow Y$  is a continuous mapping. Then the following statements are equivalent:

- (a)  $f$  is continuous.
- (b) For each closed set  $C$  of  $Y$ ,  $f^{-1}(C)$  is closed in  $X$ .

(c) For each  $x \in X$  and each neighborhood  $V$  of  $f(x)$ ,  $f^{-1}(V)$  is a neighborhood of  $x$  in  $X$ .

(d) For each  $x \in X$  and each  $V \ni f(x)$ ,  $\exists U \ni x$  such that  $f(U) \subset V$ .

(e) For each  $B \subset Y$ ,  $\overline{f^{-1}(B)} \subset f^{-1}(\overline{B})$ .

(f) For each  $A \subset X$ ,  $\overline{f(A)} \subset f(\overline{A})$ .

**Definition 1.2:** Let  $G$  be a semi topological group. Let  $a$  be any fixed element of  $G$ . Then the mappings  $r_a: x \rightarrow xa$  and  $\ell_a: x \rightarrow ax$  on  $G$  are called right and left translations respectively.

**Theorem 1.2:** Let  $G$  be a semi-topological group and  $a \in G$ . The functions from  $G$  to  $G$  are called right and left translations of  $G$  by the element  $a$  are given as

$$r_a : x \rightarrow xa \text{ and } \ell_a : x \rightarrow ax.$$

The translations of  $G$  give homeomorphism in each case.

**Proof:** In order to show that  $r_a$  is a homeomorphism. We first claim that  $r_a$  is bijective. Let  $y \in G$ , then we can write  $r_a: y \rightarrow ya$ . This mapping maps the element  $ya^{-1}$  to  $y$  by multiplying  $a^{-1}$  on the right both sides.

So  $r_a$  is surjective, as every element of co domain is mapped to at least one element of the domain that is, image and co-domain are equal.

Now we claim that  $r_a$  is injective. Assume that  $r_a(x) = r_a(y)$  for some  $x, y \in G$ .

This implies that  $xa = ya$ . Now by multiplying  $a^{-1}$  on the right, we get,  $x = y$ .

Hence,  $r_a$  is injective.

As  $G$  is a semi-topological group, then, it has continuous group operations in each variable separately.

Let  $W$  be a neighborhood of  $xa$ . Since  $G$  is a semi topological group then  $\exists U \ni x$  such that  $U_y \subset W$ .

Because, function  $r_a$  fixes  $a \in G$ , so that we get  $\forall W \in F_{xa} \exists U \in F_x$  such that  $U_y \subset W$ , this shows  $r_a$  is continuous.

Consider the inverse mapping  $r_a^{-1}(x): x \rightarrow xa^{-1}$ , which is equivalent to  $r_a : xa \rightarrow x$ . By same argument one can say  $r_a^{-1}$  is continuous. Hence,  $r_a$  is a homeomorphism. Similarly, we can show it for left translation  $\ell_a$ .

## 2. Topological Group

In this section we discuss the general results concerning topological groups, translations in topological groups and neighborhood system of the identity of topological group.

**Definition 2.2:** Let  $(G, m)$  be a group and  $\tau$  be a topology on  $G$ , then we say that  $(G, m, \tau)$  or simply  $G$  is a if the two basic operations:  $m : G \times G \rightarrow G$  defined by  $(x, y) \rightarrow m(x, y) = xy$ , and the inversion map:  $i : G \rightarrow G$  defined by  $x \rightarrow x^{-1}$  are continuous. Simply we can say if the function  $G \times G \rightarrow G$ , defined by  $(x, y) \rightarrow xy^{-1}$  is continuous. Then  $G$  is a topological group.

**Example 2.1:** A group with discrete topology is a topological group.

**Example 2.2:** The set  $R^* = R \setminus \{0\}$ , multiplication as group operation and the topology induced from  $R$ .

**Example 2.3:**  $R^+ = \{x \in R : x > 0\}$ , with a topology induced from  $R \setminus \{0\}$ . This is the subgroup of  $R \setminus \{0\}$ .

**Remark 2.1:** The continuity of function depends not only upon the function  $f$  itself, but it also depends upon the topologies on the domain and range space. For example if the topology of range space  $Y$  is given by basis  $B$ . Then in order to prove the continuity of  $f$ , it is sufficient to show that inverse image of every basis element is open.

**Theorem 2.1:** Every topological group is a semi topological group, but converse is not true always.

**Proof:** By definition, we can say that every topological group is a semi topological group. The converse is not true in general.

**Example 2.4:** Let  $G = R$ , be an additive abelian group. Let  $G$  be a set having the topology which has a basis element of form  $\{[a, b) : -\infty < a \leq x < b < \infty\}$ . This means that the topology on  $G$  is a lower limit topology. Since 0 is a identity element of  $G = R$  with respect to addition as binary operation. Clearly, for each neighbourhood  $[a, b)$  of 0. We see that  $[a, b/2)$  is also neighborhood of 0. It is suffices to show that  $g(x, y) = x + y$  is continuous in each variable separately.

Let  $U$  and  $V$  are two subsets of a group  $G$  then,

$$U + V = \{x + y : x \in U \text{ and } y \in V\} \text{ and } -U = \{-x : x \in U\}.$$

As  $g$  is continuous in  $x$  or  $y$  if and only if for each  $W \ni x + y$  there exists a neighborhood  $U \ni x$  or  $V \ni y$  such that  $Uy \subset W$  or  $xV \subset W$ .

Now,  $[a, b)$  and  $[a, \frac{b}{2})$  are neighbourhoods of 0, so it follows that  $g$  is continuous in each variable separately at 0.

Hence, by definition  $G$  is a semi-topological group. We claim that the mapping  $f: x \rightarrow x^{-1}$  is not continuous at 0. Since we know that  $f$  is continuous if for each neighborhood  $W$  of  $-x$  such that there exists a neighborhood  $V$  of  $x$  such that  $-V \subset W$ .

If  $[0, b)$  is a neighborhood of 0 then, there is no neighborhood  $V$  of 0 such that  $-V \subset [0, b)$ . Therefore,  $f$  is not continuous. Hence,  $G$  is not a topological group as desired.

**Theorem 2.2:** Let  $G$  be a topological group. Then the following statements are equivalent:

- (i)  $G$  is a  $T_0$ -space
- (ii)  $G$  is a  $T_1$ -space
- (iii)  $G$  is a Hausdorff space.

**Theorem 2.3:** Let  $f: X \rightarrow Y$  and  $g: Y \rightarrow Z$  be continuous maps, then the map  $g \circ f: X \rightarrow Z$  is continuous.

**Theorem 2.4:** Let  $G$  be a topological group. Then the following maps  $r_a: x \rightarrow xa$ ,  $\ell_a: x \rightarrow ax$ ,  $x \rightarrow x^{-1}$  and  $x \rightarrow axa^{-1}$  are homeomorphisms.

**Proof: (i)** Given that  $G$  is a topological group. Our aim is to show that  $r_a$  is a homeomorphism. We first claim that  $r_a$  is bijective. Let  $y \in G$ , then  $r_a: y \rightarrow ya$ .

This mapping maps the element  $ya^{-1}$  to  $y$  by multiplying  $a^{-1}$  on the right both sides. So  $r_a$  is surjective, as every element of co domain is mapped to at least one element of the domain that is, image and co domain are equal. Now we claim that  $r_a$  is injective.

Assume that  $r_a(x) = r_a(y)$  for some  $x, y \in G$ . This implies that  $xa = ya$ .

Now by multiplying  $a^{-1}$  on the right, we get,  $x = y$ . Hence,  $r_a$  is injective. Now, it remains to prove that  $r_a$  and its inverse are continuous.

For  $W \ni xa$ , there exists  $U \ni x$  such that  $Uy \subset W$ . So that for each  $W \in F_{xa} \exists U \in F_x$  such that  $Uy \subset W$ , this shows  $r_a$  is continuous.

Consider the inverse mapping,  $r_a^{-1}(x): x \rightarrow xa^{-1}$ , which is equivalent to  $r_a: xa \rightarrow x$ . By the similar argument,  $r_a^{-1}$  is continuous. Hence  $r_a$  is a homeomorphism by definition. Similarly we can show it for left translation  $\ell_a$ .

- (ii) The inverse mapping  $x \rightarrow x^{-1}$  is bijective.

The mapping  $x \rightarrow x^{-1}$  is continuous and clearly, the inverse map of the inverse map is itself, this means that  $x^{-1} \rightarrow x$  is continuous. Therefore, by definition of homeomorphism the map  $x \rightarrow x^{-1}$  is homeomorphism, as desired.

(iii) We want to show that the inner automorphism map  $x \rightarrow axa^{-1}$  is homeomorphism.

The mapping  $x \rightarrow axa^{-1}$  is a composition of two mappings  $x \rightarrow ax$  and  $x \rightarrow xa^{-1}$ .

We already prove these two maps homeomorphism, therefore their composition  $x \rightarrow axa^{-1}$  is also homeomorphism, because composition mapping is always continuous.

### 3. Neighborhood System

**Definition 3.1:** Let  $X$  be a topological space, let  $x \in X$  be any arbitrary point. A subset  $V$  of  $X$  is said to a neighborhood of  $x$ , if there exists an open set  $U$  such that  $x \in U \subset V$ .

**Example 3.1:** The closed interval  $[0,1]$  is a neighborhood of  $0.5$ , but not a neighborhood of  $0$ .

**Example 3.2:** Consider set  $X = \{p, q, r, s, t\}$  with  $\tau_X = \{X, \phi, \{p, q, r\}, \{p, q, r, s\}, \{s\}\}$ , then clearly  $p, q \in X$  has exactly three neighbourhoods as given follows:

- (a)  $p, q \in A = \{p, q, r\} \in \tau_X$
- (b)  $p, q \in B = \{p, q, r, s\} \in \tau_X$
- (c)  $p, q \in C = X \in \tau_X$

So  $p$  and  $q$  has three open neighbourhoods.

**Remark 3.1:** Neighborhood of a point is not always an open set, clearly, every open set is a neighborhood of each of its point, because a set is called open if it is the neighborhood of every point.

**Theorem 3.1:** A subset  $A$  of  $X$  is open iff for each  $x \in X, \exists V \ni x$  such that  $V \subset A$ .

**Definition 3.2:** Let  $(X, \tau)$  be a space. Let  $x \in X$  be any arbitrary point. Consider  $U$  be the set of all neighbourhoods of  $x$ . Let  $V \subset U$ , then  $V$  is said to be a *fundamental system of neighbourhoods* of  $x$ , if for each  $U_1 \in U$  there exists some  $V_1 \in V$  such that  $V_1 \subset U_1$ . we call  $V$  as a base for  $U$ .

**Remark 3.2:** Let  $X$  be a space, then for  $x \in X$ , let  $U$  denotes the set all neighbourhoods of  $x$ . Then following properties are established by using definitions of neighbourhoods and open set:

- (a) For each  $U_1$  in  $U, x \in U_1$ .

(b) If  $U_1 \in U$  and  $W$  is any subset of  $X$  such that  $U \subset W$ , then  $W \in U$ .

(c) Every finite intersection of sets in  $U$  is also in  $U$ .

**Definition 2.3: (Symmetric neighborhood)** Let  $G$  be a topological group with identity  $e$ . A neighborhood  $V$  of  $e$  said to be symmetric if  $V^{-1} = V$ .

**Definition 3.4: (Symmetric subset)** Symmetric subset: Let  $G$  be group and  $S$  be any non-empty subset of  $G$ . then  $S$  is said to be symmetric if  $S = S^{-1}$ , where  $S^{-1} = \{x^{-1} : x \in S\}$ . In other words,  $S$  is symmetric if  $x^{-1} \in S$ , whenever  $x \in S$ .

**Example 3.3:** Let  $G = R$ , the intervals  $(-a, a)$  with  $a > 0$  are symmetric sets.

**Example 3.4:** The set  $\{-1, 1\}$  is a symmetric set.

**Remark 3.3:** Let  $S$  be the symmetric subset of a topological group  $G$ . Then,

(a) The identity element  $e$  lies inside the subset, that is,  $e \in S$ .

(b) The inverse of any element of subset  $S$  of  $G$  also lies inside the subset, that is, if  $x \in S$  then  $x^{-1} \in S$ .

**Theorem 3.2:** Let  $G$  be topological Group with identity  $e$ . Then there exists a fundamental system of neighbourhoods of identity element  $e$  of  $G$  in  $G$ .

**Proof:** We have given that  $G$  is topological group with identity  $e$ . Let  $A$  be the fundamental system of open neighbourhoods of identity  $e$  of  $G$ . Then our aim is to prove that there exists a symmetric subset  $A_1$  of  $A$  that satisfies the condition of fundamental system of neighbourhoods. Let  $A_1$  be the open set of  $A$ . Then for the group  $G$  be a topological group. Then the maps  $r_a : x \rightarrow xa$ ,  $l_a : x \rightarrow ax$  and  $x \rightarrow axa^{-1}$  are homeomorphisms: The third mapping is homeomorphism. Since  $e \in G$ , then the inverse mapping  $e \rightarrow e^{-1}$  is also homeomorphism. As  $A$  is open neighborhood of  $e$ , then  $A^{-1}$  will be open neighborhood of  $e^{-1}$ . But we know the identity of a group is unique, so  $e^{-1} = e$ . Therefore, we can say that  $A$  and  $A^{-1}$  are two open neighbourhoods of identity element  $e$ .

Now assume that  $S = A \cap A^{-1}$ . Then,

$$S^{-1} = (A \cap A^{-1})^{-1} = A^{-1} \cap (A^{-1})^{-1} = A^{-1} \cap A = S.$$

This implies that  $S^{-1} = S$ .

So,  $S$  is symmetric neighborhood of  $x$ . Since  $A$  and  $A^{-1}$  are open, then so is their intersection  $S$ . We have  $S = A \cap A^{-1}$  is the open neighborhood of  $e$ , because  $A$  and  $A^{-1}$  are open neighbourhoods of  $e$ . Thus for each  $A_1 \in \mathcal{A}$ , there is some  $S$  with  $S \subset A_1$ . The set of all such  $S$  forms a fundamental system of symmetric neighbourhoods of  $e$ .

**Remark 2.4:** Let  $G$  be a topological group with identity  $e$ . If  $A$  and  $B$  are subsets of  $G$ . Then we define the set  $A * B$  as follows:

$$A * B = \{a * b : a \in A, b \in B\} \text{ and } A^{-1} = \{x^{-1} : x \in A\}.$$

**Theorem 2.3:** Let  $G$  be the topological group and  $e$  be its identity. Then, every neighborhood of identity  $e$  in the topological group contains the product of a symmetric neighborhood of identity with itself.

**Proof:** Let  $(G, \tau, \cdot)$  be a topological group, and  $e$  be its identity element. Suppose that  $U$  is the neighborhood of  $e$ . Claim that there exists a symmetric neighborhood  $V$  of the  $e$  such that  $V.V \subset U$ .

Let  $V$  be a symmetric neighborhood of  $e$ . By definition of symmetric neighborhood,  $V = V^{-1}$ , where  $V^{-1} = \{v^{-1} : v \in V\}$ . This implies that  $V^{-1}$  is neighborhood of  $e$ . Suppose that  $V$  is the open neighborhood of  $e$  contained in  $U$ . Note that  $V.V^{-1}$  is an open set as  $V$  is an open set, then obviously  $V.V^{-1}$  will be open neighborhood of  $e$ . Also  $(V.V^{-1})^{-1} = V^{-1}.V$ , implies that  $V.V^{-1}$  is symmetric. Since,  $V$  and  $V^{-1}$  are open neighbourhoods of  $e$  contained in  $U$ . So that,  $V.V^{-1} \subset U$ .
