### Abstract

An assignment of integers to the vertices of a graph G is called a vertex labeling of G. The concept of graph labeling plays a vital role in computer and network security. A graph G on n vertices is said to admit a divisor 3-equitable labeling if

there exists a bijection 
$$d: V(G) \to \{1, 2, ..., n\}$$
 defined by  $d(e = xy) = \begin{cases} 1, if d(x)|d(y) \text{ or } d(y)|d(x) \\ 2, & \text{if } \frac{d(x)}{d(y)} = 2 \text{ or } \frac{d(y)}{d(x)} = 2 \text{ and } |e_d(i) - e_d(j)| \le 0, \\ 0, & \text{otherwise} \end{cases}$ 

1 for all  $0 \le i, j \le 2$ . A graph which permits a divisor 3-equitable labeling is called a divisor 3-equitable graph. A graph  $K_n$  in which "every pair of vertices is adjacent" is called a complete graph and a complete bipartite graph  $K_{1,n}$  is known as a star graph. In this paper, we prove the non-existence of a divisor 3-equitable labeling of the complete graph  $K_n$  for  $n \ge 1$ 5 and star graph  $K_{1,n}$  for  $n \ge 6$ .

**Keywords:** 3-equitable labeling, divisor 3-equitable labeling, complete graph, star graph

# 1. Introduction

All graphs considered in this present investigation are finite, undirected, simple, and connected. By G(V, E), or simply G, we mean a graph G with "vertex set V and edge set E." We also denote the "number of vertices in G" by |V(G)| and the "number of edges in G" by |E(G)|. An assignment of integers to the vertices of G is called a vertex labeling of G. Graph labeling is a "strong communication" between the structure of graphs and number theory. Labeled graphs have a variety of applications in coding theory such as "missile guidance codes, design of good radar type codes, convolution codes with optimal auto correlation properties" etc. Labeled graphs also play a vital role in the field of X -ray crystallography, in determining optimal circuit layouts, and communication networks [4].

### **Definition 1.** [2]

Let a and b be any two integers. If "a divides b", then that there is k (a "positive integer") such that b = ka and denoted by  $a \mid b$ . If "a does not divide b", then it is denoted by  $a \nmid b$ .

# Theorem 1. [2] (The Division Algorithm)

If a, b are integers with b > 0, then there exist "unique integers" q, r such that  $a = q \cdot b + r$  with  $0 \le r < b$ where q is called the "quotient" and r is called the "remainder".

I. Cahit introduced the notion of "cordial labeling" in 1987. For a detailed study on cordial graphs and 3-equitable labeling, one can refer to [1, 2].

# **Definition 2.** [3]

"A labeling (vertex)  $f: V \to \{0,1\}$  induces another labeling (edge)  $f * : E \to \{0,1\}$  defined by f \* (xy) = f(x) - f(x)f(y). For  $i \in \{0,1\}$ , let  $v_f(i)$  and  $e_f(i)$  be the number of vertices v and edges e with f(v) = i and f \* (e) = i, respectively. A graph G is cordial if there exists a labeling (vertex) f such that  $v_f(0) - v_f(1) \le 1$  and  $e_f(0) - e_f(1) \le 1$ 1".

By merging the "divisibility concept in number theory and cordial labeling concept in graph labeling", Varatharajan et al. [6] introduced a new notion called "divisor cordial labeling" and proved various results. The definition of a divisor cordial labeling is given below.

## **Definition 3.** [6]

Let G = (V, E) be the given graph and  $f : V(G) \to \{1, 2, ..., |V|\}$  be a bijective function. For each edge uv, assign the label "1" if either  $f(u) \mid f(v)$  or  $f(v) \mid f(u)$  and the label "0" otherwise. Then f is called a "divisor cordial labeling" if  $|e_f(0) - e_f(1)| \le 1.$ 

Further, in 2019, Sweta Srivastav and Sangeeta Gupta [5] introduced a new variant of graph labeling called a "divisor 3equitable labeling" which is defined as follows.

# **Definition 4.** [5]

A divisor 3-equitable labeling is a "bijection"  $d:V(G) \to \{1,2,\ldots,n\}$  defined by

$$d\left(e=xy\right) = \begin{cases} 1, if d(x)|d(y) \text{ or } d(y)|d(x) \\ 2, & if \frac{d(x)}{d(y)} = 2 \text{ or } \frac{d(y)}{d(x)} = 2 \text{ such that } |e_d(i) - e_d(j)| \le 1 \text{ for all } 0 \le i, j \le 2, \text{ where } e_d(i) \text{ is the otherwise} \end{cases}$$

number of edges labeled with label "i". A graph which permits a divisor 3-equitable labeling is called a "divisor 3equitable graph".

In this paper, we prove that the complete graph  $K_n$  for  $n \ge 4$  and star graph  $K_{1,n}$  for  $n \ge 6$  do not admit a divisor 3equitable labeling.

# 2. Main Results

In this section, first we recall a few important definitions and results concerning the divisor 3-equitable labeling of graphs which are relevant to the study undertaken. We also prove the non-existence of a divisor 3-equitable labeling of complete graph and star graph.

## **Theorem 2.** [5]

The path  $P_n$  is a divisor 3-equitable graph.

# **Theorem 3.** [5]

The cycle  $C_n$  is a divisor 3- equitable graph.

# 2.1. Divisor 3-Equitable Labeling of Complete Graphs

This section is devoted for proving the non-existence of the divisor 3-equitable labeling of complete graphs. First we recall the definition of a complete graph.

# **Definition 5.**

The "complete graph  $K_n$ " is a graph in which "any two vertices are adjacent".

One can easily obtain the divisor 3-equitable labeling of  $K_1$ ,  $K_2$ ,  $K_3$ , and  $K_4$ . One such example is given in Figure 1. So we consider  $K_n$ , for  $n \ge 5$ .

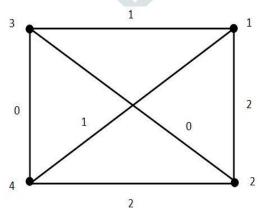

Figure 1. A divisor 3-equitable labeling of the complete graph  $K_4$ 

# Theorem 4.

A complete graph  $K_n$  does not permit a divisor 3-equitable labeling for all  $n \ge 5$ .

#### Proof.

Let  $K_n = \{v_1, v_2, ..., v_n\}$  be the given complete graph on  $n \ge 5$  vertices. One can clearly observe that any two vertices in

$$K_n$$
 are adjacent. In other words, a vertex  $v \in K_n$  is adjacent to all other vertices of  $K_n$ . Now define a bijection  $d: V(K_n) \to \{1, 2, ..., n\}$  defined by  $d(e = xy) = \begin{cases} 1, if d(x) | d(y) \text{ or } d(y) | d(x) \\ 2, & if \frac{d(x)}{d(y)} = 2 \text{ or } \frac{d(y)}{d(x)} = 2$ . We prove this theorem by a method of otherwise

contradiction. Let's assume that  $K_n, n \ge 5$  has a divisor 3-equitable labeling d such that " $|e_d(i) - e_d(j)| \le 1$ " for all  $0 \le i, j \le 2$ . Note that a vertex labeled with 1 in  $K_n$ , say  $d(v_1) = 1$ , is adjacent to all other vertices,  $v_i : 2 \le i \le n$ labeled with 2, 3, ..., n in any possible permutation. So as per the definition of a divisor 3-equitable labeling, if the label of a vertex  $v_1$ , say  $d(v_1)$ , divides the label of the adjacent vertex  $v_2$ , say  $d(v_2)$ , then the edge  $v_1v_2$  must be given the label 1. As the vertex  $v_1$  is adjacent to all other vertices in  $K_n$ , it gives 1 as the edge label to all other edges except the edge whose end vertex is labeled with 2, say  $v_2$ , (in which case the edge label is 2 as per the definition) in  $K_n$  which are incident on  $v_1$ . That is.,  $d(v_1v_i) = 1$  for all  $3 \le i \le n$ , a contradiction to the fact that  $|e_d(i) - e_d(j)| \le 1$  for all  $0 \le n$  $i, j \leq 2$ . Therefore, a complete graph  $K_n$  does not permit a divisor 3-equitable labeling for all  $n \geq 5$ .

# 2.2. Divisor 3-Equitable Labeling of Star Graphs

This section is devoted to prove the non-existence of a divisor 3-equitable labeling of the star graphs.

#### **Definition 6.**

A star graph  $S_{n+1}$  is defined as a complete bipartite graph  $K_{1.n}$ .

One can clearly obtain the "divisor 3-equitable labeling of  $K_{1,n}$ ,  $1 \le n \le 5$ ." One such example is given in Figure 2.

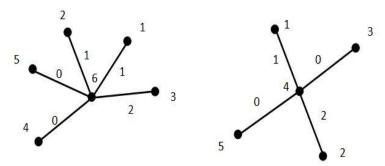

Figure 2. A divisor 3-equitable labeling of  $K_{1,5}$  and  $K_{1,4}$ 

#### Theorem 5.

A star graph  $K_{1,n}$  does not permit a divisor 3-equitable labeling for all  $n \ge 6$ .

#### Proof.

Let  $K_{1,n}$  be the given star graph on  $n \ge 6$  vertices. We take n = 6 for the sake of discussion and so  $|V(K_{1,6})| =$ 7 and  $|E(K_{1,6})| = 6$ . One can note that there are six vertices of degree one and a vertex of degree 6 in  $K_{1,6}$ . We label the central vertex as  $v_0$  and pendant vertices as  $v_1, v_2, ..., v_6$ . Now define a bijective function  $d: V(K_{1,6}) \rightarrow$ 

central vertex as 
$$v_0$$
 and pendant vertices as  $v_1, v_2, ..., v_6$ . Now define a bijective function  $d: V(K_{1,6}) \to \{1, 2, ..., 7\}$  defined by  $d(e = xy) = \begin{cases} 1, if d(x)|d(y) \text{ or } d(y)|d(x) \\ 2, & \text{if } \frac{d(x)}{d(y)} = 2 \text{ or } \frac{d(y)}{d(x)} = 2 \text{ . We prove by the method of contradiction. Let us } \\ 0, & \text{otherwise} \end{cases}$ 

assume that  $K_{1,6}$  has a divisor 3-equitable labeling d with the property that  $|e_d(i) - e_d(j)| \le 1$  for all  $0 \le i, j \le 1$ 2. One can also observe that the number of edges labeled with label either 0 or 1 or 2 can be at most 2 (as there are exactly seven vertices in  $K_{1,6}$ ) to satisfy the required divisor 3-equitable property  $|e_d(i) - e_d(j)| \le 1$  for all  $0 \le i, j \le 1$ 2. Now arises the following seven cases.

**Case 1:** When  $d(v_0) = 1$ 

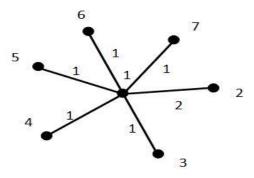

Figure 3. The central vertex in  $K_{1,6}$  is labeled with 1

As the central vertex is adjacent to all other vertices and the label 1 divides all other labels,  $d(v_0v_i) = 1$  for all  $2 \le i \le 6$  and  $d(v_0v_1) = 2$ . So the number of edges labeled with 1 is 5, a contradiction.

**Case 2:** When  $d(v_0) = 2$ 

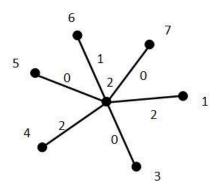

Figure 4. The central vertex in  $K_{1,6}$  is labelled with 2

One can note that there are three edges with label 0, two edges with label 2, and only one vertex with label 1, a contradiction. This is because  $|e_d(0) - e_d(2)| \le 1$  but  $|e_d(0) - e_d(1)| = 2$ .

**Case 3:** When  $d(v_0) = 3$ 

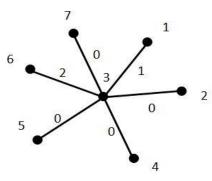

Figure 5. The central vertex in  $K_{1,6}$  is labelled with 3

Interestingly there are four edges with label 0, one edge with label 1, and an edge with label 2, a contradiction as the number of edges labeled with 0 is more than 2.

**Case 4:** When  $d(v_0) = 4$ 

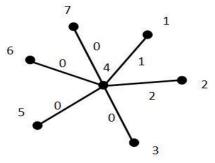

Figure 6. The central vertex in  $K_{1,6}$  is labelled with 4

This is a similar case as Case 3.

**Case 5:** When  $d(v_0) = 5$ 

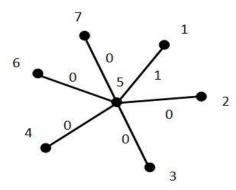

Figure 7. The central vertex in  $K_{1,6}$  is labeled with 5

Interestingly there are five edges with label 0 and an edge with label 1, a contradiction.

**Case 6:** When  $d(v_0) = 6$ 

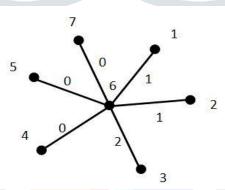

Figure 8. The central vertex in  $K_{1,6}$  is labelled with 6

Now there are three edges with label 0, two edges with label 1, and an edge with label 2, again a contradiction because  $|e_d(0) - e_d(1)| \le 1$  but  $|e_d(0) - e_d(2)| = 2$ .

**Case 7:** When  $d(v_0) = 7$ 

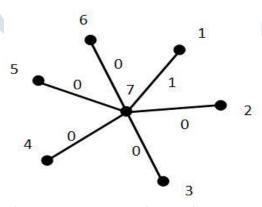

Figure 9. The central vertex in  $K_{1,6}$  is labelled with 7

Here there are five edges of label 0 and an edge of label 1, a clear contradiction. Hence  $K_{1,n}$ , when n = 6 does not admit a divisor 3-equitable labeling. A similar argument holds good for any  $n \ge 7$ .

# 3. Conclusion

The existence and non-existence of a divisor 3-equitable labeling of complete graphs and star graphs are established. Investigating divisor 3-equitable labeling of other classes of graphs is still open and this is for future research. We believe that the concept of divisor 3-equitable labeling may play a vital role in computer security. One can also explore the exclusive applications of divisor 3-equitable labeling in real life situations.
