ABSTRACT: Super-resolution from a single frame is a required task in many computer vision systems. Super resolution is the process of recovering a high-resolution (HR) image from single image or multiple low-resolution (LR) images of the same scene. The main aim of super resolution (SR) is to increase better visual quality of available low resolution image. The SR image approaches reconstruct a single higher-resolution image from a set of given lower-resolution images. There is a basic need for digital images of higher resolutions and quality. In this paper, surveys of various methods of super resolution have been done. A super resolution method which is generate high-resolution (HR) image from one or more low resolution images and various image quality metrics reviewed as measure the original image and reconstructed image.

1. INTRODUCTION

Image super resolution is a image processing algorithms that produce high quality, high resolution (HR) images from a set of low quality, low resolution (LR) images or from a single image. The SR image reconstruction is useful in many practical cases where multiple frames of the same scene can be obtained, including medical imaging, satellite imaging, and video applications[17].The basic premise for increasing the spatial resolution in SR techniques is the availability of multiple LR images captured from the same scene. The set of source low resolution (LR) images captures only a finite amount of information from a scene; the goal of SR is to extract the independent information from each image in that set and combine the information into a single high resolution (HR) image. The requirement is of SR is that each LR must contain some information that is unique to that image[3]. The super resolution method is to take more samples of the scene so as to get some extra information which can be used, while merging the samples to get a high resolution image. These samples can be acquired by sub-pixel shifts, by changing scene , by changing the amount of blur[14].HR means that pixel density within an image is high, and therefore an HR image can offer more details that are important in many applications. The major advantage of the super resolution approach is that it may cost less and the existing LR imaging systems can be still utilized. Synthetic zooming of region of interest (ROI) is another important application in surveillance, forensic, scientific, medical, and satellite imaging[13]. This application is most suitable for magnifying objects in the scene such as the face of a criminal or the license plate of a car [16].

2. LITERATURE SURVEY

[1] Y. Sun Et-al, presented a compressive sensing based on a redundant dictionary has been successfully applied in super resolution imaging. However, due to the neglect of the local and nonlocal interactions of patches of a single image, the reconstructed results are not satisfactory in noise suppression and edge sharpness. In this paper, we propose an improved method by adding steering kernel regression and a nonlocal means filter as two regularization terms and use an efficient clustering sub-dictionary learning scheme. We further demonstrate better results on true images in terms of traditional image quality assessment metrics.

[2] Y. Sun Et-al, presented an observation for medical imaging and astronomical, high-resolution (HR) images are urgently desired and required. In recent years, many researchers have proposed various ways to achieve the goal of image super-resolution (SR), ranging from simple linear interpolation schemes to nonlinear complex methods. In this paper, we deal with the SR reconstruction problem based on the theory of compressive sensing, which uses a redundant dictionary instead of a conventional orthogonal basis. We further demonstrate better results on true images in terms of peak signal-to-noise ratio (PSNR) and root-mean-square error (RMSE) and give several important improvements, compared with other methods.

[3] M. Agrawal et-al, presented a technique for enhancing resolution of images by interpolating high frequency sub-bands generated using lifting wavelet transform (LWT) and spatial information of input low resolution (LR) image. Stationary wavelet transform (SWT) is used at intermediate stage for edge enhancement. The input image is decomposed using LWT in order to generate high frequency (HF) sub-bands. The generated HF subbands are interpolated further. Different high frequency sub-bands obtained through SWT are added to correct the estimated HF subbands. The input LR image is interpolated in parallel. All these sub-bands and estimated LR image are reconstructed by inverse lifting wavelet transformation (ILWT) to produce high resolution image. The qualitative, quantitative and visual images of the described technique show the superiority of the proposed method over conventional and state-of-the-art methods.
A. Interpolation Methods

Image interpolation is the process of converting the image from one resolution to other resolution. This process is performed on a one dimension basis row by row and then column by column. Image interpolation estimates the intermediate pixel between the known pixels by using different interpolation kernel.

- **Nearest Neighbor Interpolation**

Nearest neighbor interpolation is the simplest interpolation from the computational point of view. In this, each output interpolated pixel assigns the value of nearest sample point in the input image. This process just displaces the intensity from reference to interpolated one so it does not change the histogram. It preserves the sharpness and dose not produce the blurring effect but produce aliasing.

- **Bi-linear Interpolation**

In Bi-linear interpolation the intensity at a point is determined from weighted some of intensity at four pixel closest to it. It changes the intensity so histogram is also change. It slightly smooths the image but does not create an aliasing effect.

- **Bi-cubic Interpolation**

In cubic interpolation intensity at point is estimated from the intensity of 16 closest to it. The basis function is Bi-cubic gives smooth image but computationally demanding.

- **B-spline Interpolation**

Spline interpolation is the form of interpolation where interpolant is a special piecewise polynomial called a spline. There is a whole family of the basis function used in interpolation which is given as [2]. Higher order interpolation is much more used when image required many rotation and distortion in separate step. However, for single step enhancement is increased processing time.

- **Hybrid Approach of Interpolation**

In 2008, H. Aftab et al. [3] proposed a new hybrid interpolation method in which the interpolation at edges is carried out using the covariance based method and interpolation at smooth area is done by using iterative curvature based method. After finding edges and smooth area using information from the neighborhood pixels edge is interpolated using covariance based method. The covariance coefficient of HR image is obtained using covariance parameter of LR image. In smooth are a curvature interpolation is carried out by first performing bilinear interpolation along the direction where the second derivative is lower and in diagonal case the difference between diagonal is calculated and use bilinear interpolation where the intensity difference is less. This method has significant advantage in terms of the processing time, peak signal to noise ratio and visual quality compared to bilinear, bi-cubic and nearest neighbor.

B. Iterative back projection algorithm

In this algorithm [1]-[3] back projection error is used to construct super resolution image. In this approach the HR image is estimated by back projecting the error between the simulated LR image and captured LR image. This process is repeated several times to minimize the cost function and each step estimate the HR image by back-projecting the error. The main advantage of this method is that this method converges rapidly, less complexity and low-less number of iteration is required. In recently numbers of improvements are used with this approach which is different edge preserving mechanisms.

C. Robust Learning-Based Super-Resolution

This algorithm [5] synthesizes a high-resolution image based on learning patch pairs of low- and high-resolution images. However, since a low-resolution patch is usually mapped to multiple high-resolution patches, unwanted artifacts or blurring can appear in...
super-resolved images. In this paper, a novel approach to generate a high quality, high-resolution image without introducing noticeable artifacts. Introducing robust statistics to a learning-based super-resolution, we efficiently reject outliers which cause artifacts. Global and local constraints are also applied to produce a more reliable high-resolution image. Learning-based super-resolution algorithms are generally known to provide HR images of high quality. However, their practical problem is the one-to-one multiple mapping of an LR patch to HR patches, which results in image quality degradation.

D. An Efficient Example-Based Approach for Image Super-Resolution

This algorithm [6], [7] uses learning method to construct super-resolution image. The main contributions of these algorithms are: (1) a class-specific predictor is designed for each class in our example-based super-resolution algorithm, this can improve the performance in terms of visual quality and computational cost; and (2) different types of training set are investigated so that a more effective training set can be obtained. The classification is performed based on vector quantization (VQ), and then a simple and accurate predictor for each category, i.e. a class-specific predictor, can be trained easily using the example patch-pairs of that particular category. These classespecific predictors are used to estimate, and then to reconstruct, the high-frequency components of a HR image. Hence, having classified a LR patch into one of the categories, the high-frequency content can be predicted without searching a large set of LR-HR patch-pairs.

E. Learning Based Super Resolution using Directionlets

In this algorithm [9] example based method using directionlets (skewed anisotropic wavelet transform) are used to generate high-resolution image. It does scaling and filtering along a selected pair of direction not necessary horizontal and vertical like wavelet transform. In this approach the training set is generated by subdividing HR images and LR images into the patches of size 8*8 and 4*4 respectively. And then best pair of the direction is assign to each pair from five set of directions [(0,0),(0,45),(45,45),(90,45)] and then grouping the patches according to direction which reduce the searching time. Input LR image is contrast normalized and then subdivided into 4*4 patches. Each patch is decomposed into eight bands passing using directionlets. The directional coefficient of six bands HL,HH,VL,VH,DL,DL are learn from training set. Minimum absolute difference MAD criterion is used to select the directionlets coefficient. For AL and AH cubic interpolated LR image is used. These learned coefficients are used to obtain SR image by taking inverse directionlets transform. At the end contrast normalize is undo. Simple wavelet which is isotropic and does not follow the edges results in the artifacts which are removed in this case.

4. CONCLUSION

The SR imaging has been one of the fundamental image processing research areas. It can overcome or compensate the inherent hardware limitations of the imaging system to provide a clearer image with a richer and informative content. It can also be served as an appreciable front-end pre-processing stage to facilitate various image processing applications to improve their targeted terminal performance. In this survey paper, our goal is to offer new perspectives and out looks of SR imaging research, besides giving an updated overview of existing SR algorithms. It is our hope that this work could inspire more image processing researchers endeavoring on this fascinating topic and developing more novel SR techniques along the way. Hence, we propose a wavelet based super-resolution technique, which will be of the category of interpolative methods. It will be based on sparse representation property of the wavelets.
