ABSTRACT— In this paper presents Improve Power Quality of Grid Connected Unbalance loads Employing Dual Voltage Source Converters. The proposed scheme is comprised of two inverters back to back connection, which enables the microgrid to exchange power generated by the distributed energy resources and also to compensate the local unbalanced and nonlinear load. The control algorithms are developed based on fuzzy logic control theory to operate dual voltage source converters in grid sharing and grid injecting modes. The proposed scheme has increased reliability, lower cost due to reduction in filter size, and better utilization of microgrid power while using reduced dc-link voltage rating for the main inverter. These features make the DVIS scheme a promising option for microgrid supplying nonlinear and unbalance loads. The Simulation results are discussed adopting MATLAB software.

Index Terms — Power quality, dual voltage source inverter, instantaneous symmetrical component theory, microgrid.

I. INTRODUCTION:
Technological progress and environmental concerns drive the power system to a paradigm shift with more renewable energy sources integrated to the network by means of distributed generation (DG). These DG units with coordinated control of local generation and storage facilities form a microgrid [1]. In a microgrid, power from different renewable energy sources such as fuel cells, photovoltaic (PV) systems, and wind energy systems are interfaced to grid and loads using power electronic converters. A grid interactive inverter plays an important role in exchanging power from the microgrid to the grid and the connected load [2], [3]. This microgrid inverter can either work in a grid sharing mode while supplying a part of local load or in grid injecting mode, by injecting power to the main grid. Maintaining power quality is another important aspect which has to be addressed while the microgrid is connected to the main grid. The proliferation of power electronics devices and electrical loads with unbalanced nonlinear currents has degraded the power quality in the power distribution network. Moreover, if there is a considerable amount of feeder impedance in the distribution systems, the propagation of these harmonic currents distorts the voltage at the point of common coupling (PCC). At the same instant, industry automation has reached to a very high level of sophistication, where plants like automobile manufacturing units, and semiconductor industries require clean power. For these applications, it is essential to compensate nonlinear and unbalanced load currents [4].

II. LITERATURE SURVEY:
Load compensation and power injection using grid interactive inverters in microgrid have been presented in the literature [5], [6]. A single inverter system with power quality enhancement is discussed in [7]. The main focus of this work is to realize dual functionalities in an inverter that would provide the active power injection from a solar PV system and also works as an active power filter, compensating unbalances and the reactive power required by other loads connected to the system. In [8], a voltage regulation and power flow control scheme for a wind energy system (WES) is proposed. A distribution static compensator (DSTATCOM) is utilized for voltage regulation and also for active power injection. The control scheme maintains the power balance at the grid terminal during the wind variations using sliding mode control. A multifunctional power electronic converter for the DG power system is described in this scheme. The microgrid has the capability to inject power generated by WES and also to perform as a harmonic compensator. Most of the reported literature in this area discuss the topologies and control algorithms to provide load compensation capability in the same inverter in addition to their active power injection. When a grid-connected inverter is used for active power injection as well as for load compensation, the inverter capacity that can be utilized for achieving the second objective is decided by the available instantaneous microgrid real power. Considering the case of a grid-connected PV inverter, the available capacity of the inverter to supply the reactive power becomes less during the maximum solar insolation periods. At the same instant, the reactive power to regulate the PCC voltage is very much needed during this period. It indicates that providing multi functionalities in a single inverter degrades either the real power injection or the load compensation capabilities.
III. DUAL VOLTAGE SOURCE INVERTER:

The proposed DVSI topology is shown in Fig. 1. It consists of a neutral point clamped (NPC) inverter to realize AVSI and a three-leg inverter for MVSI [18]. These are connected to grid at the PCC and supplying a nonlinear and unbalanced load. The function of the AVSI is to compensate the reactive, harmonics, and unbalance components in load currents. Here, load currents in three phases are represented by $i_{la}$, $i_{lb}$, and $i_{lc}$, respectively. Also, $i_{g\mu gm}(abc)$, and $i_{g\mu gx}(abc)$ show grid currents, MVSI currents, and AVSI currents in three phases, respectively. The dc link of the AVSI utilizes a split capacitor topology, with two capacitors $C_1$ and $C_2$. The MVSI delivers the available power at distributed energy resource (DER) to grid. The DER can be a dc source or an ac source with rectifier coupled to dc link. Usually, renewable energy sources like fuel cell and PV generate power at variable low dc voltage, while the variable speed wind turbines generate power at variable ac voltage. Therefore, the power generated from these sources use a power conditioning stage before it is connected to the input of MVSI. In this study, DER is being represented as a dc source.

Values of dc capacitors of AVSI are chosen based on the change in dc-link voltage during transients. Let total load rating is $S$ kVA. In the worst case, the load power may vary from minimum to maximum, i.e., from 0 to $S$ kVA. AVSI needs to exchange real power during transient to maintain the load power demand. This transfer of real power during the transient will result in deviation of capacitor voltage from its reference value. Assume that the voltage controller takes $n$ cycles, i.e., $nT$ seconds to act, where $T$ is the system time period. Hence, maximum energy exchange by AVSI during transient will be $nST$.

Advantages of DVSI scheme is Increased Reliability, reduction of filter size, improved flexibility, better utilization of microgrid power, reduced DC link voltage.

IV. Fuzzy Logic Controller

Fuzzy logic is a new control approach with great potential for real time applications. Fig. 4.3 shows the structure of the fuzzy logic controller (FIS-Fuzzy inference system) in MATLAB Fuzzy logic toolbox. Load voltage and load current taken as input to fuzzy system. For a closed loop control, error input can be selected as current, voltage or impedance, according to control type. To get the linearity triangular membership function is taken with 50% overlap. The output of fuzzy controller taken as the control signal and the pulse generator provides synchronous firing pulses to thyristors as shown in fig. The Fuzzy Logic is a rule based controller, where a set of rules represents a control decision mechanism to correct the effect of certain causes coming from power system. In fuzzy logic, the five linguistic variables expressed by fuzzy sets defined on their respective universes of discourse. Table-I shows the suggested membership function rules of FC-TCR controller. The rule of this table can be chosen based on practical experience and simulation results observed from the behavior of the system around its stable equilibrium points.

V. SIMULATION RESULTS:

Proposed power system network with dual voltage source converters are shown in figure.2.

VI. CONCLUSION:

Voltage Source Converter scheme is proposed for microgrid systems with enhanced power quality. Control algorithms are developed to generate reference currents for Dual converters using ISCT. The proposed scheme has the capability to exchange power from distributed generators (DGs) and also to compensate the local unbalanced and nonlinear load. The performance of the proposed scheme has been validated through simulation and experimental studies. As compared to a single inverter with multifunctional capabilities, a VSI has many advantages such as, increased reliability, lower cost due to the reduction in filter size, and more utilization of inverter capacity to inject real power from DGs to microgrid. Moreover, the use of three-phase, three wire topology for the main inverter reduces the dc-link voltage requirement. Thus, a Dual VSI scheme is a suitable interfacing option for microgrid supplying sensitive loads.
