ABSTRACT

A series of important amide non-urea inhibitors of soluble epoxide hydrolase (sEH) is disclosed. QSAR studies have been performed on forty-three molecules of derivatives. QSAR models have been evaluated for piperidine derivatives guided optimization of a lead compounds. In this work, we used multiple linear regression (MLR) procedure to derive 2D-QSAR models that show a strong correlation between piperidine derived non-urea soluble epoxide hydrolase inhibitors and various topological descriptors.

Key words: Non-urea inhibitors, SAR, MLR, QSAR

1 INTRODUCTION

Soluble epoxide hydrolase (sEH) may be a bifunctional homodimeric catalyst with hydrolase and enzyme activity detected in varied species starting from plants to mammals.[1] In humans it's principally situated in liver, kidney, internal organ and vascular tissues.[2] The sEH catalyst is selective for acyclic epoxides of fatty acids, and one among the foremost vital substrates is epoxyeicosatrienoic acid (EET).[3] EETs ar one among the metabolic derivatives of arachidonic acid.[4] The epoxygenase CYP2 enzymes turn the epoxydation of olefine bonds of arachidonic acid generating EETs.[5] EETs exhibit vasodilatory effects in varied arteries [6,7] and possess anti-inflammatory drug properties.[8] sEH mediates the addition of water to EETs, changing them to the corresponding diols—dihydroxyeicosatrienoic acids (DHETs), that show abolished or diminished biological activity.

The inhibition of this catalyst, so might represent a promising therapeutic strategy since it might result in elevated levels of EETs, that might then have helpful therapeutic effects on pressure and inflammation.[9] the foremost explored sEH inhibitors thus far ar urea-based compounds and various structure–activity relationship (SAR) studies crystal rectifier to discovery of many potent urea-based sEH inhibitors with IC50s within the lower nanomolar vary.[10,11] but, the ureabased inhibitors usually suffer from poor solubility and stability, that hinders their medical specialty use in vivo.[12,13] Amides, carbamates and thioureas are evaluated as different pharmacophores in an endeavor to enhance physical properties of urea-based inhibitors. during this report we have a tendency to disclose our efforts towards coming up with novel non-urea, amide-based inhibitors of

sEH. The underneath study compounds with the biological activity were taken from Stevan Pecic et. al. [14]

2. RESULTS AND DISCUSSION

Developing a QSAR model requires a diverse set of data, and thereby, a large number of descriptors have to be considered.[15] Descriptors are numerical values that encode different structural features of the molecules. A key step in QSAR modeling is evaluating model's stability and prediction ability. We used cross-validation and external test set for these proposes. Cross-validation has different variants such as leave-one-out (LOO), leavegroup-out (LGO) and m-fold. It was shown previously that LOO can lead to chance and over fitted models whereas LGO is more sensitive to chance variables.

Therefore, we used LGO for model-validation utilizing correlation coefficient and root mean square error of cross-validation as scoring function. In addition, an external test set composed of 24 molecules was also used. The molecules in this set did not have contribution in the model step and thus their predicted values can give a final prediction power of the models as measured by regression coefficient, standard error, fisher criterion, adjusted regression coefficient and cross validated regression coefficient.

First, separate stepwise selection-based MLR analysis were performed using different types of descriptors, and then, an MLR equation was obtained utilizing the pool of all calculated descriptors. MLR models for subsets of molecules (Table 4.1.3) provide the obtained equations for training set series of 39 compounds. In this series, the geometrical parameters did not represent a significant impact on the biological activity. The Calculated indices had a moderate impact on the HDAC inhibitory activity of according to a medium R^2 for the corresponding QSAR model. The equations obtained from topological and indicator descriptors were predictive. Pearson's correlation matrix has been performed on all descriptors by using NCSS 12.0 statistics software.

Table 3: Correlation Matrix Between Descriptors and Inhibitory Activity

In QSAR study on the studied molecules, this compound has also detected as no outlier. (Table 4.1.5) describe the QSAR models resulted for 24 compounds using different

sets of descriptors. Again, among the groups of descriptors obtained from the whole molecular structure, the topological indices resulted in a significant QSAR model for predicting HDAC inhibitory activity of the studied molecules. It has a good statistical quality for predicting the activity of the inhibitors. The analysis of the matrix revealed six descriptors for the development of MLR models. The values of descriptors used in MLR analysis are presented in Table 4.1.1.

Model No.1

$IC_{50} = -225.9833(\pm 59.2891) + 70.8233(\pm 16.10556) S_3K$

| n | r | Se | F-Ratio | R ² CV | Adj R ² |
|----|--------|-------|---------|-------------------|--------------------|
| 41 | 0.5757 | 47.51 | 19.338 | 0.1231 | 0.3143 |
| | | E | | R | |

From QSAR model No.1 the low statistical results indicates needs for the development of Biparametric or more multiparametric QSAR models follow by rule of thumb. Here, equations for topological descriptors were statistically acceptable. The effect of topological descriptors on the inhibitory activity sulfonamide derivatives of the compounds are described by QSAR Model No.1. The QSAR model no.1 has significant importance in which S_3K has positive contribution with the IC₅₀ inhibitory activity.

Model No.2

 $IC_{50} = 64.2457(\pm 212.4396) + 68.5109(\pm 15.9820) S_3K - 328.8767(\pm 231.4121) BLI$

| n | r | Se | F-Ratio | R ² CV | Adj R ² |
|----|--------|--------|----------------|-------------------|--------------------|
| 41 | 0.6043 | 46.900 | 10.931 | 0.1361 | 0.3318 |

Model No.3

 $IC_{50} = 3130.9727 (\pm 1846.072) + 97.1128(\pm 23.1646) S_3K - 446.9083(\pm -446.9084) BLI$

– 584.4829 (±-584.483) MAXDN

| n | r | Se | F-Ratio | R ² CV | Adj R ² |
|----|--------|---------|---------|-------------------|--------------------|
| 41 | 0.6401 | 45.8309 | 8.564 | 0.1829 | 0.3619 |

The QSAR model No.2 and QSAR model No.3 show their significant statistical importance with biparametic and triparametric model in which BLI and MAXDN is inversely proportional with the IC_{50} inhibitory activity while S_3K is directly proportional with the IC_{50} inhibitory activity.

Model No.4

 $IC_{50} = 4509.4859 (\pm 2056.668) + 82.5614(\pm 24.97) S_3K - 649.7552(\pm 272.78) BLI$ - 812.7006(±379.39) MAXDN + 1.2799(±0.8895) BAC R²CV **F-Ratio** Adj R² Se n r 41 0.3799 0.6647 45.18 0.1230 7.126 Model No.5 $IC_{50} = 9102.9147 (\pm 2782.14) + 42.9153 (\pm 29.1922) S_3K - 500.4046 (\pm 265.757) BLI$ - 1768.6708(±547.90)MAXDN + 2.7593(±1.0571)BAC $+ 0.6800(\pm 0.2947)$ ZM₂Kup **F-Ratio** R²CV Adj R² Se n 0.4464 41 0.7180 42.69 0.2501 7.450

The above described all models are not statistically excellent indicates the deletion of outliers compounds whose activity are not uniform and after deleting the compound no. 13 and 23 resulting the development of high statistically QSAR model no.5 indicates the importance of topological descriptors in IC_{50} inhibitory activity.

After deleting compounds no. 13 and 23

QSAR Model No.5

IC₅₀ = 7732.8856(±1585.535) + 19.7891(±16.755) S₃K - 479.5779(±150.77) BLI - 1487.2284(±312.526) MAXDN + 3.5259(±0.6055) BAC

 $+ 0.5450(\pm 0.1695)$ ZM₂Kup

| n | r | Se | F-Ratio | R ² CV | Adj R ² |
|----|--------|-------|----------------|-------------------|--------------------|
| 39 | 0.8665 | 24.19 | 19.895 | 0.4144 | 0.7131 |

The randomization test suggests that the developed model have a probability less than 1% that the model is generated by chance. The observed IC_{50} activity and Predicted IC_{50} activity along with residual values are shown in Table 4. The plot of observed vs. Predicted activity is shown in figure 2. From the plot it can be seen that the MLR model is able to predict the activity of set of compounds as well as external.

The above study leads to the development of statistically significant QSAR model, which allows understanding of the molecular properties/features that play an important role in governing the variation in the activities. In addition, this QSAR study allowed investigating influence of very simple and easy to compute descriptors in determing biological activites, which could shed light on the key factors that may aid in design of novel potent molecules.

Figure 3: Ridge Regression between Descriptors and Biological Activity CONCLUSION

Structure–activity relationship of the lead reveals some particular structural requirements to the left hand side part of the piperidine amide base sEH inhibitors.

- 1. A varying degree of bulky, non- polar cycloalkyl rings are well tolerated in this region by target enzyme.
- 2. Proper substitution on the phenyl ring is crucial for attaing good potency, emphasizing the importance of the small non polar groups and halogens in para position as a recognition element of sEH.
- 3. The left hand side phenyl is in a relatively close proximity to a several hydrophobic residue located in the large, nonpolar pocket of sEH that opens towards solvent, and probably participating in a pi stacking interaction with them.
