**Abstract:** In this paper, we introduce a new class of sets called  $\pi g g \zeta^*$ -closed sets in topological spaces. Also we study and investigate the relationship with other existing closed sets. Moreover, we introduce some functions such as  $g \zeta^*$ -closed,  $\pi g g \zeta^*$ -closed, almost  $g \zeta^*$ -closed, almost  $\pi g g \zeta^*$ -closed,  $\pi g g \zeta^*$ -continuous and almost  $\pi g g \zeta^*$ -continuous. We also study a new class of normal space called, quasi  $g \zeta^*$ -normal space. The relationships among normal,  $\pi$ -normal, quasi normal, softly normal, mildly normal,  $\alpha$ -normal,  $\pi \alpha$ -normal, quasi  $\alpha$ -normal, softly  $\alpha$ -normal, mildly  $\alpha$ -normal,  $g \zeta^*$ -normal,  $\pi g \zeta^*$ -normal, quasi  $g \zeta^*$ -normal, softly  $g \zeta^*$ -normal and mildly  $g \zeta^*$ -normal spaces are investigated. Further we show that this property is a topological property and it is a hereditary property only with respect to closed domain subspaces. Utilizing  $\pi g g \zeta^*$ -closed sets and some functions, we obtained some characterizations and preservation theorems for quasi  $g \zeta^*$ -normal spaces.

**2010 AMS Subject classification :** 54D15, 54D10, 54A05, 54C08.

**Keywords :**  $\pi$ -open,  $g \zeta^*$ -open,  $\pi g g \zeta^*$ -open,  $\pi$ -closed,  $g \zeta^*$ -closed, and  $\pi g g \zeta^*$ -closed sets;  $\pi g g \zeta^*$ -closed, almost  $\pi g g \zeta^*$ -closed,  $\pi g g \zeta^*$ -continuous and almost  $\pi g g \zeta^*$ -continuous functions; quasi  $g \zeta^*$ -normal spaces.

## 1. Introduction

In 1965, Njastad [13] introduced the concept of  $\alpha$ -open sets in topological spaces. In 1968, the notion of quasi normal space was introduced by Zaitsev [21]. In 1970, Levine [11] initiated the study of so called generalized closed (briefly  $g$ -closed) sets in order to extend many of the most important properties of closed sets to a large family. In 1973, Singal and Singal [20] introduced the notion of mildly normal spaces in topological spaces. In 1990, Lal and Rahman [10] have further studied notions of quasi normal and mildly normal spaces. In 1994, H. Maki et al. [12] introduced the notion of  $\alpha g$ -closed sets. In 2000, Dontchev and Noiri [4] introduced the notion of  $\pi g$ -closed sets and by using these sets, obtained a new characterization of quasi normal space. In 2001, A. V. Arhangel'skii and Ludwig [1] introduced the concepts of  $\alpha$ -normal and  $\beta$ -normal spaces. In 2004, Nono et al. [15] introduced the notion of  $g^\# \alpha$ -closed sets in topological spaces. In 2007, Arockiarani and C. Janaki [2] introduced the notion of  $\pi g \alpha$ -closed sets in topological spaces and by using  $\pi g \alpha$ -closed sets, obtained a new characterization of quasi  $\alpha$ -normal spaces. In 2008, Kalantan [6] introduced a weaker version of normality called  $\pi$ -normality and proved that  $\pi$ -normality is a property which lies between normality and almost normality. In 2009, R. Devi et al. [3] introduced the notion of  $g^\# \alpha$ -closed sets in topological spaces. In 2013, Kokilavani [7] introduced the notion of  $g \zeta^*$ -closed sets in topological spaces and investigated some of their properties. In 2015, T. C. K. Raman [16] introduced the concepts of  $\pi \alpha$ -normal spaces. In 2018, Hamant Kumar [5] introduced some normal spaces such as  $g \zeta^*$ -normal,  $\pi g \zeta^*$ -normal, quasi  $g \zeta^*$ -normal and mildly  $g \zeta^*$ -normal, and the relationships among these normal spaces are investigated.

## 2. Preliminaries

Throughout this paper, spaces  $(X, \mathfrak{T})$ ,  $(Y, \sigma)$ , and  $(Z, \gamma)$  (or simply  $X$ ,  $Y$  and  $Z$ ) always mean topological spaces on which no separation axioms are assumed unless explicitly stated. Let  $A$  be a subset of a space  $X$ . The closure of  $A$  and interior of  $A$  are denoted by  $\text{cl}(A)$  and  $\text{int}(A)$  respectively. A subset  $A$  is said to be **regular open** (resp. **regular closed**) if  $A = \text{int}(\text{cl}(A))$  (resp.  $A = \text{cl}(\text{int}(A))$ ). The finite union of regular open sets is said to be  **$\pi$ -open**. The complement of a  $\pi$ -open set is said to be  **$\pi$ -closed**.  $A$  is said to be  **$\alpha$ -open** [13] if  $A \subset \text{int}(\text{cl}(\text{int}(A)))$ . The complement of a  $\alpha$ -open set is said to be  **$\alpha$ -closed**. The intersection of all  $\alpha$ -closed sets containing  $A$  is called  **$\alpha$ -closure** [13] of  $A$ , and is denoted by  $\alpha\text{-cl}(A)$ . The  **$\alpha$ -interior** [13] of  $A$ , denoted by  $\alpha\text{-int}(A)$ , is defined as union of all  $\alpha$ -open sets contained in  $A$ .

**2.1 Definition.** A subset  $A$  of a space  $(X, \mathfrak{T})$  is said to be

- (1) **generalized closed** (briefly **g-closed**) [11] if  $\text{cl}(A) \subset U$  whenever  $A \subset U$  and  $U \in \mathfrak{T}$ .
- (2)  **$\pi$ g-closed** [4] if  $\text{cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $\pi$ -open in  $X$ .
- (3)  **$\alpha$ -generalized closed** (briefly  **$\alpha$ g-closed**) [12] if  $\alpha\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U \in \mathfrak{T}$ .
- (4)  **$\pi\alpha$ -closed** [2] if  $\alpha\text{cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $\pi$ -open in  $X$ .
- (5) **generalized  $\#$  $\alpha$ -closed** (briefly  **$g^\#\alpha$ -closed**) [15] if  $\alpha\text{-cl}(A) \subset U$  whenever  $A \subset U$  and is  $g$ -open in  $X$ .
- (6)  **$\#$ generalized  $\alpha$ -closed** (briefly  **$\#g\alpha$ -closed**) [3] if  $\alpha\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $g^\#\alpha$ -open in  $X$ .
- (7)  **$g\zeta^*$ -closed** [7] if  $\alpha\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $\#g\alpha$ -open in  $X$ .
- (8)  **$g$ -open** (resp.  **$\pi$ g-open,  $\alpha$ g-open,  $\pi\alpha$ -open,  $g^\#\alpha$ -open,  $\#g\alpha$ -open,  $g\zeta^*$ -open) set if the complement of  $A$  is  $g$ -closed (resp.  $\pi$ g-closed,  $\alpha$ g-closed,  $\pi\alpha$ -closed,  $g^\#\alpha$ -closed,  $\#g\alpha$ -closed,  $g\zeta^*$ -closed).**

The intersection of all  $g\zeta^*$ -closed sets containing  $A$  is called  **$g\zeta^*$ -closure of  $A$** , and is denoted by  $g\zeta^*\text{-cl}(A)$ . The  **$g\zeta^*$ -interior of  $A$** , denoted by  $g\zeta^*\text{-int}(A)$ , is defined as union of all  $g\zeta^*$ -open sets contained in  $A$ . The family of all  $g\zeta^*$ -closed (resp.  $g\zeta^*$ -open) sets of a space  $X$  is denoted by  $g\zeta^*\text{-C}(X)$  (resp.  $g\zeta^*\text{-O}(X)$ ).

**2.2 Definition.** A subset  $A$  of a space  $(X, \mathfrak{T})$  is said to be

- (1) **generalized  $g\zeta^*$ -closed** [9] (briefly **gg $\zeta^*$ -closed**) if  $g\zeta^*\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U \in \mathfrak{T}$ .
- (2)  **$\pi$ -generalized  $g\zeta^*$ -closed** (briefly  **$\pi$ gg $\zeta^*$ -closed**) if  $g\zeta^*\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $\pi$ -open in  $X$ .

**2.3 Remark.** We have the following implications for the properties of subsets:

$$\begin{array}{ccccc}
 \text{closed} & \Rightarrow & g\text{-closed} & \Rightarrow & \pi g\text{-closed} \\
 \Downarrow & & \Downarrow & & \Downarrow \\
 \alpha\text{-closed} & \Rightarrow & \alpha g\text{-closed} & \Rightarrow & \pi \alpha\text{-closed} \\
 \Downarrow & & \Downarrow & & \Downarrow \\
 g\zeta^*\text{-closed} & \Rightarrow & gg\zeta^*\text{-closed} & \Rightarrow & \pi gg\zeta^*\text{-closed}
 \end{array}$$

Where none of the implications is reversible as can be seen from the following examples:

**2.4 Example.** Let  $X = \{a, b, c\}$  and  $\mathfrak{T} = \{\emptyset, \{a\}, X\}$ . Then  $A = \{b\}$  is  $g$ -closed as well as  $\alpha g$ -closed. Hence  $A$  is  $gg\zeta^*$ -closed. But it is not closed.

**2.5 Example.** Let  $X = \{a, b, c, d\}$  and  $\mathfrak{T} = \{\emptyset, \{a\}, \{d\}, \{a, d\}, \{c, d\}, \{a, c, d\}, X\}$ . Then  $A = \{c\}$  is  $\pi g\alpha$ -closed as well as  $\pi gg\zeta^*$ -closed but not  $g$ -closed.

**2.6 Example.** Let  $X = \{a, b, c, d\}$  and  $\mathfrak{T} = \{\emptyset, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{a, d\}, \{a, b, c\}, \{a, b, d\}, \{a, c, d\}, X\}$ . Then  $A = \{a\}$  is  $\pi g\alpha$ -closed as well as  $\pi gg\zeta^*$ -closed but not closed.

**2.7 Example.** Let  $X = \{a, b, c, d\}$  and  $\mathfrak{T} = \{\emptyset, \{c\}, \{d\}, \{a, c\}, \{c, d\}, \{a, c, d\}, X\}$ . Then  $A = \{a\}$  is  $\alpha$ -closed as well as  $\alpha g$ -closed. Hence  $A$  is  $g\zeta^*$ -closed. But it is not closed.

**2.8 Example.** Let  $X = \{a, b, c\}$  and  $\mathfrak{T} = \{\emptyset, \{a\}, \{b, c\}, X\}$ . Then  $A = \{b\}$  is  $\alpha g$ -closed as well as  $gg\zeta^*$ -closed. But it is not  $g\zeta^*$ -closed.

**2.9 Theorem.** For  $\pi gg\zeta^*$ -closed sets of a space  $X$ , the following properties hold:

- Every finite union of  $\pi gg\zeta^*$ -closed sets is always a  $\pi gg\zeta^*$ -closed set.
- Even a countable union of  $\pi gg\zeta^*$ -closed sets need not be a  $\pi gg\zeta^*$ -closed set.
- Even a finite intersection of  $\pi gg\zeta^*$ -closed sets may fail to be a  $\pi gg\zeta^*$ -closed set.

**Proof.**

(a) Let  $A$  and  $B$  be any two  $\pi gg\zeta^*$ -closed sets. Therefore  $g\zeta^*\text{-cl}(A) \subset U$  and  $g\zeta^*\text{-cl}(B) \subset U$  whenever  $A \subset U$ ,  $B \subset U$  and  $U$  is  $\pi$ -open. Let  $A \cup B \subset U$  where  $U$  is  $\pi$ -open.

Since,  $g\zeta^*\text{-cl}(A \cup B) \subset g\zeta^*\text{-cl}(A) \cup g\zeta^*\text{-cl}(B) \subset U$ , we have  $A \cup B$  is  $\pi gg\zeta^*$ -closed.

(b) Let  $R$  be the real line with the usual topology. Every singleton is  $\pi gg\zeta^*$ -closed. However,  $A = \{1/i : i = 2, 3, \dots\}$  is not  $\pi gg\zeta^*$ -closed, since  $A \subset (0, 1)$  which is  $\pi$ -open but  $g\zeta^*\text{-cl}(A) \not\subset (0, 1)$ .

(c) Let  $X = \{a, b, c, d\}$  and let  $\mathfrak{T} = \{\emptyset, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}, \{a, b, d\}, X\}$ . Let  $A = \{a, b, c\}$  and  $B = \{a, b, d\}$  are  $\pi gg\zeta^*$ -closed sets. But  $A \cap B = \{a, b\} \subset \{a, b\}$  which is  $\pi$ -open.  $g\zeta^*\text{-cl}(A \cap B) \not\subset \{a, b\}$ . Hence  $A \cap B$  is not  $\pi gg\zeta^*$ -closed.

**2.10 Theorem:** If  $A$  is  $\pi gg\zeta^*$ -closed and  $A \subset B \subset g\zeta^*\text{-cl}(A)$  then  $B$  is  $\pi gg\zeta^*$ -closed.

**Proof:** Since  $A$  is  $\pi gg\zeta^*$ -closed,  $g\zeta^*\text{-cl}(A) \subset U$  whenever  $A \subset U$  and  $U$  is  $\pi$ -open. Let  $B \subset U$  and  $U$  is  $\pi$ -open. Since  $B \subset g\zeta^*\text{-cl}(A)$ ,  $g\zeta^*\text{-cl}(B) \subset g\zeta^*\text{-cl}(A) \subset U$ . Hence  $B$  is  $\pi gg\zeta^*$ -closed.

**2.11 Theorem.** Let  $A$  be a  $\pi gg\zeta^*$ -closed set in  $X$ . Then  $g\zeta^*\text{-cl}(A) - A$  does not contain any nonempty  $\pi$ -closed set.

**Proof.** Let  $F$  be a nonempty  $\pi$ -closed set such that  $F \subset g\zeta^*\text{-cl}(A) - A$ . Then  $F \subset g\zeta^*\text{-cl}(A) \cap (X - A) \subset (X - A)$  implies  $A \subset X - F$  where  $X - F$  is  $\pi$ -open. Therefore  $g\zeta^*\text{-cl}(A) \subset X - F$  implies  $F \subset (g\zeta^*\text{-cl}(A))^c$ . Now  $F \subset g\zeta^*\text{-cl}(A) \cap (g\zeta^*\text{-cl}(A))^c$  implies  $F$  is empty.

Reverse implication does not hold.

**2.12 Example.** Let  $X = \{a, b, c, d, e\}$  and let  $\mathfrak{T} = \{\emptyset, \{a, b\}, \{c, d\}, \{a, b, c, d\}, X\}$ . Let  $A = \{c\}$  then  $g\zeta^*$ - $cl(A) = \{c, d, e\}$ ,  $g\zeta^*$ - $cl(A) - A = \{d, e\}$  does not contain any nonempty regular closed set but  $A$  is not  $\pi gg\zeta^*$ -closed set.

**2.13 Corollary.** Let  $A$  be  $\pi gg\zeta^*$ -closed.  $A$  is  $g\zeta^*$ -closed iff  $g\zeta^*$ - $cl(A) - A$  is  $\pi$ -closed.

**Proof.** Let  $A$  be  $g\zeta^*$ -closed set then  $A = g\zeta^*$ - $cl(A)$  implies  $g\zeta^*$ - $cl(A) - A = \emptyset$  which is  $\pi$ -closed.

Conversely, if  $g\zeta^*$ - $cl(A) - A$  is  $\pi$ -closed then  $A$  is  $g\zeta^*$ -closed.

**2.14 Theorem.** If  $A$  is  $\pi$ -open and  $\pi gg\zeta^*$ -closed. Then  $A$  is  $g\zeta^*$ -closed and hence clopen.

**Proof.** Let  $A$  be regular open. Since  $A$  is  $\pi gg\zeta^*$ -closed,  $g\zeta^*$ - $cl(A) \subset A$  implies  $A$  is  $g\zeta^*$ -closed. Hence  $A$  is closed. (Since every  $\pi$ -open  $g\zeta^*$ -closed set is closed). Therefore  $A$  is clopen.

**2.15 Theorem.** For a space  $X$ , the following are equivalent:

- (a)  $X$  is extremally disconnected,
- (b) Every subset of  $X$  is  $\pi gg\zeta^*$ -closed
- (c) The topology on  $X$  generated by  $\pi gg\zeta^*$ -closed set is the discrete one.

**Proof.** (a)  $\Rightarrow$  (b).

Assume that  $X$  is extremally disconnected. Let  $A \subset U$  where  $U$  is  $\pi$ -open in  $X$ . Since  $U$  is  $\pi$ -open, it is the finite union of regular open sets and  $X$  is extremally disconnected,  $U$  is finite union of clopen sets and hence  $U$  is clopen. Therefore  $g\zeta^*$ - $cl(A) \subset cl(A) \subset cl(U) \subset U$  implies  $A$  is  $\pi gg\zeta^*$ -closed.

(b)  $\Rightarrow$  (a)

Let  $A$  be a regular open set of  $X$ . Since  $A$  is  $\pi gg\zeta^*$ -closed by **Theorem 2.14**,  $A$  is clopen. Hence  $X$  is extremally disconnected.

(b)  $\Leftrightarrow$  (c) is obvious.

### 3. $\pi gg\zeta^*$ -open sets

**3.1 Definition.** A subset  $A$  of a space  $X$  is called  $\pi$ -generalized  $g\zeta^*$ -open (briefly  $\pi gg\zeta^*$ -open) iff its complement is  $\pi gg\zeta^*$ -closed set.

**3.2 Lemma.** If  $A$  be a subset of  $X$ , then

- (a)  $g\zeta^*$ - $cl(X - A) = X - g\zeta^*$ - $int(A)$ .
- (b)  $g\zeta^*$ - $int(X - A) = X - g\zeta^*$ - $cl(A)$ .

**3.3 Theorem.** A subset  $A$  of a space  $X$  is  $\pi gg\zeta^*$ -open iff  $F \subset g\zeta^*$ - $int(A)$  whenever  $F$  is  $\pi$ -closed and  $F \subset A$ .

**Proof.** Let  $F$  be  $\pi$ -closed set such that  $F \subset A$ . Since  $X - A$  is  $\pi gg\zeta^*$ -closed and  $X - A \subset X - F$  where  $F \subset g\zeta^*$ - $int(A)$ . Conversely,

Let  $F \subset g\zeta^*$ - $int(A)$  where  $F$  is  $\pi$ -closed and  $F \subset A$ . Since  $F \subset A$  and  $X - F$  is  $\pi$ -open,  $g\zeta^*$ - $cl(X - A) = X -$

$g\zeta^*\text{-int}(A) \subset X - F$ . Therefore  $A$  is  $\pi g\zeta^*$ -open.

**3.4 Theorem.** If  $g\zeta^*\text{-int}(A) \subset B \subset A$  and  $A$   $\pi g\zeta^*$ -open then  $B$  is  $\pi g\zeta^*$ -open.

**Proof:** Since  $g\zeta^*\text{-int}(A) \subset B \subset A$ , by **Theorem 2.10**,  $g\zeta^*\text{-cl}(X - A) \supset (X - B)$  implies  $B$  is  $\pi g\zeta^*$ -open.

**3.5 Remark.** For any  $A \subset X$ ,  $g\zeta^*\text{-int}(g\zeta^*\text{-cl}(A) - A) = \emptyset$ .

**3.6 Theorem.** If  $A \subset X$  is  $\pi g\zeta^*$ -closed then  $g\zeta^*\text{-cl}(A) - A$  is  $\pi g\zeta^*$ -open.

**Proof.** Let  $A$  be  $\pi g\zeta^*$ -closed and  $F$  be a  $\pi$ -closed set such that  $F \subset g\zeta^*\text{-cl}(A) - A$ . By **Theorem 2.11**,  $F = \emptyset$

implies  $F \subset g\zeta^*\text{-int}(g\zeta^*\text{-cl}(A) - A)$ . By **Theorem 3.3**,  $g\zeta^*\text{-cl}(A) - A$  is  $\pi g\zeta^*$ -open.

Converse of the above theorem is not true.

**3.7 Example.** Let  $X = \{a, b, c\}$  and let  $\mathfrak{T} = \{\emptyset, \{a\}, \{b\}, \{a, b\}, X\}$ . Let  $A = \{b\}$ . Then  $A$  is not  $\pi g\zeta^*$ -closed but  $g\zeta^*\text{-cl}(A) - A = \{a, b\}$  is  $\pi g\zeta^*$ -open.

## 4. Quasi $g\zeta^*$ -normal spaces

**4.1 Definition.** A space  $X$  is said to be  **$g\zeta^*$ -normal** [18] (resp.  **$\alpha$ -normal** [1]) if for every pair of disjoint closed subsets  $A, B$  of  $X$ , there exist disjoint  $g\zeta^*$ -open (resp.  $\alpha$ -open) sets  $U, V$  of  $X$  such that  $A \subset U$  and  $B \subset V$ .

**4.2 Definition.** A space  $X$  is said to be  **$\pi g\zeta^*$ -normal** [5] (resp.  **$\pi$ -normal** [6],  **$\pi\alpha$ -normal** [16]) if for every pair of disjoint closed subsets  $A, B$  of  $X$ , one of which is  $\pi$ -closed, there exist disjoint  $g\zeta^*$ -open (resp. open,  $\alpha$ -open) sets  $U, V$  of  $X$  such that  $A \subset U$  and  $B \subset V$ .

**4.3 Definition.** A space  $X$  is said to be **quasi  $g\zeta^*$ -normal** [5] (resp. **quasi normal** [21], **quasi  $\alpha$ -normal** [2]) if for every pair of disjoint  $\pi$ -closed subsets  $H, K$  of  $X$ , there exist disjoint  $g\zeta^*$ -open (resp. open,  $\alpha$ -open) sets  $U, V$  of  $X$  such that  $H \subset U$  and  $K \subset V$ .

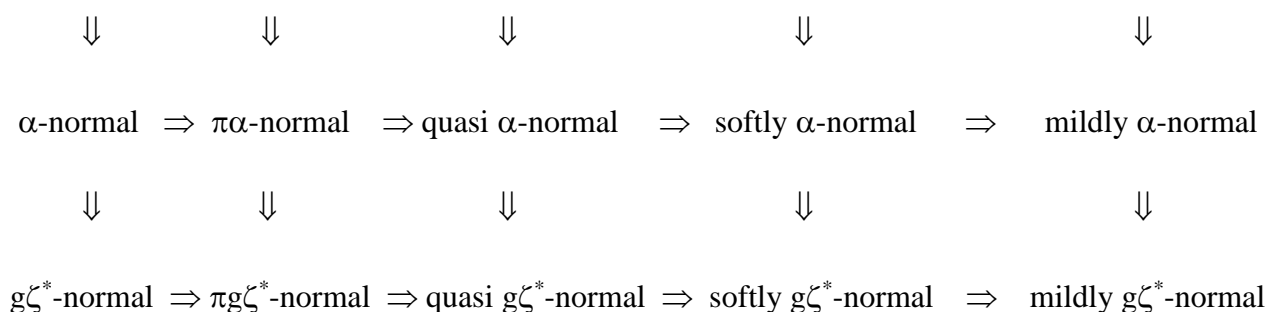

**4.4 Definition.** A space  $X$  is said to be **softly  $g\zeta^*$ -normal** [5] (resp. **softly normal** [17], **softly  $\alpha$ -normal**) if for every pair of disjoint subsets  $A, B$  of  $X$ , one of which is  $\pi$ -closed and the other is regularly closed, there exist disjoint  $g\zeta^*$ -open (resp. open,  $\alpha$ -open) sets  $U, V$  of  $X$  such that  $A \subset U$  and  $B \subset V$ .

**4.5 Definition.** A space  $X$  is said to be **mildly  $g\zeta^*$ -normal** [18] (resp. **mildly-normal** [20], **mildly  $\alpha$ -normal** [2]) if for every pair of disjoint regular closed subsets  $H, K$  of  $X$ , there exist disjoint  $g\zeta^*$ -open (resp. open,  $\alpha$ -open) sets  $U, V$  of  $X$  such that  $H \subset U$  and  $K \subset V$ .

**By the definitions stated above, we have the following diagram:**

normal  $\Rightarrow$   $\pi$ -normal  $\Rightarrow$  quasi-normal  $\Rightarrow$  softly normal  $\Rightarrow$  mildly-normal

Where none of the implications is reversible as can be seen from the following examples:

**4.6 Example.** Let  $X = \{a, b, c, d\}$  and  $\mathfrak{T} = \{\emptyset, \{a, b\}, \{c, d\}, X\}$ . The pair of disjoint closed subsets of  $X$  are  $A = \{a, b\}$  and  $B = \{c, d\}$ . Also  $U = \{a, b\}$  and  $V = \{c, d\}$  are open sets such that  $A \subset U$  and  $B \subset V$ . Hence the space  $X$  is normal as well as  $\alpha$ -normal. It is also  $g\zeta^*$ -normal.

**4.7 Example.** Let  $X = \{a, b, c, d\}$  and  $\mathfrak{T} = \{\emptyset, \{a\}, \{c\}, \{a, c\}, \{a, b, d\}, \{b, c, d\}, X\}$ . The pair of disjoint closed subsets of  $X$  are  $A = \{a\}$  and  $B = \{c\}$ . Also  $U = \{a\}$  and  $V = \{c\}$  are open sets such that  $A \subset U$  and  $B \subset V$ . Hence the space  $X$  is normal as well as  $\alpha$ -normal, since every open set is  $\alpha$ -open.

**4.8 Theorem.** For a space  $X$ , the following are equivalent:

- (a)  $X$  is quasi  $g\zeta^*$ -normal.
- (b) For every pair of  $\pi$ -open subsets  $U$  and  $V$  of  $X$  whose union is  $X$ , there exist  $g\zeta^*$ -closed subsets  $G$  and  $H$  of  $X$  such that  $G \subset U, H \subset V$  and  $G \cup H = X$ .
- (c) For any  $\pi$ -closed set  $A$  and every  $\pi$ -open set  $B$  in  $X$  such that  $A \subset B$ , there exists a  $g\zeta^*$ -open subset  $U$  of  $X$  such that  $A \subset U \subset g\zeta^*\text{-cl}(U) \subset B$ .
- (d) For every pair of disjoint  $\pi$ -closed subsets  $A$  and  $B$  of  $X$ , there exist  $g\zeta^*$ -open subsets  $U$  and  $V$  of  $X$  such that  $A \subset U, B \subset V$  and  $g\zeta^*\text{-cl}(U) \cap g\zeta^*\text{-cl}(V) = \emptyset$ .

**Proof.** (a)  $\Rightarrow$  (b), (b)  $\Rightarrow$  (c), (c)  $\Rightarrow$  (d) and (d)  $\Rightarrow$  (a).

(a)  $\Rightarrow$  (b). Let  $U$  and  $V$  be any  $\pi$ -open subsets of a quasi  $g\zeta^*$ -normal space  $X$  such that  $U \cup V = X$ . Then,  $X - U$  and  $X - V$  are disjoint  $\pi$ -closed subsets of  $X$ . By quasi  $g\zeta^*$ -normality of  $X$ , there exist disjoint  $g\zeta^*$ -open subsets  $U_1$  and  $V_1$  of  $X$  such that  $X - U \subset U_1$  and  $X - V \subset V_1$ . Let  $G = X - U_1$  and  $H = X - V_1$ . Then,  $G$  and  $H$  are  $g\zeta^*$ -closed subsets of  $X$  such that  $G \subset U, H \subset V$  and  $G \cup H = X$ .

(b)  $\Rightarrow$  (c). Let  $A$  be a  $\pi$ -closed and  $B$  is a  $\pi$ -open subsets of  $X$  such that  $A \subset B$ . Then,  $X - A$  and  $B$  are  $\pi$ -open subsets of  $X$  such that  $(X - A) \cup B = X$ . Then, by part (b), there exist  $g\zeta^*$ -closed sets  $G$  and  $H$  of  $X$  such that  $G \subset (X - A), H \subset B$  and  $G \cup H = X$ . Then,  $A \subset (X - G), (X - B) \subset (X - H)$  and  $(X - G) \cap (X - H) = \emptyset$ . Let  $U = X - G$  and  $V = (X - H)$ . Then  $U$  and  $V$  are disjoint  $g\zeta^*$ -open sets such that  $A \subset U \subset X - V \subset B$ . Since  $X - V$  is  $g\zeta^*$ -closed, then we have  $g\zeta^*\text{-cl}(U) \subset (X - V)$ . Thus,  $A \subset U \subset g\zeta^*\text{-cl}(U) \subset B$ .

(c)  $\Rightarrow$  (d). Let  $A$  and  $B$  be any disjoint  $\pi$ -closed subset of  $X$ . Then  $A \subset X - B$ , where  $X - B$  is  $\pi$ -open. By the part (c), there exists a  $g\zeta^*$ -open subset  $U$  of  $X$  such that  $A \subset U \subset g\zeta^*\text{-cl}(U) \subset X - B$ . Let  $V = X - g\zeta^*\text{-cl}(U)$ . Then,  $V$  is a  $g\zeta^*$ -open subset of  $X$ . Thus, we obtain  $A \subset U, B \subset V$  and  $g\zeta^*\text{-cl}(U) \cap g\zeta^*\text{-cl}(V) = \emptyset$ .

(d)  $\Rightarrow$  (a). It is obvious.

**4.9 Proposition.** Let  $f : X \rightarrow Y$  be a function, then:

- (a) The image of  $g\zeta^*$ -open subset under an open continuous function is  $g\zeta^*$ -open.
- (b) The inverse image of  $g\zeta^*$ -open (resp.  $g\zeta^*$ -closed) subset under an open continuous function is  $g\zeta^*$ -open (resp.  $g\zeta^*$ -closed) subset.
- (c) The image of  $g\zeta^*$ -closed subset under an open and a closed continuous surjective function is  $g\zeta^*$ -open.

**4.10 Theorem.** The image of a quasi  $g\zeta^*$ -normal space under an open continuous injective function is a quasi  $g\zeta^*$ -normal.

**Proof.** Let  $X$  be a quasi  $g\zeta^*$ -normal space and let  $f : X \rightarrow Y$  be an open continuous injective function. We need to show that  $f(X)$  is a quasi  $g\zeta^*$ -normal. Let  $A$  and  $B$  be any two disjoint  $\pi$ -closed sets in  $f(X)$ . Since the inverse image of a  $\pi$ -closed set under an open continuous function is a  $\pi$ -closed. Then,  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint  $\pi$ -closed sets in  $X$ . By quasi  $g\zeta^*$ -normality of  $X$ , there exist  $g\zeta^*$ -open subsets  $U$  and  $V$  of  $X$  such that  $f^{-1}(A) \subset U$ ,  $f^{-1}(B) \subset V$  and  $U \cap V = \emptyset$ . Since  $f$  is an open continuous injective function, we have  $A \subset f(U)$ ,  $B \subset f(V)$  and  $f(U) \cap f(V) = \emptyset$ . By **Proposition 4.9**, we obtain  $f(U)$  and  $f(V)$  are disjoint  $g\zeta^*$ -open sets in  $f(X)$  such that  $A \subset f(U)$  and  $B \subset f(V)$ . Hence  $f(X)$  is quasi  $g\zeta^*$ -normal.

From the above theorem, we have the following corollary.

**4.11 Corollary.** Quasi  $g\zeta^*$ -normality is a topological property.

The following lemma helps us to show that quasi  $g\zeta^*$ -normality is a hereditary with respect to closed domain subspaces.

**4.12 Lemma.** Let  $M$  be a closed domain subspace of a space  $X$ . If  $A$  is a  $g\zeta^*$ -open set in  $X$ , then  $A \cap M$  is  $g\zeta^*$ -open set in  $M$ .

**4.13 Theorem.** Quasi  $g\zeta^*$ -normality is a hereditary with respect to closed domain subspaces.

**Proof.** Let  $M$  be a closed domain subspace of a quasi  $g\zeta^*$ -normal space  $X$ . Let  $A$  and  $B$  be any disjoint  $\pi$ -closed sets in  $M$ . Since  $M$  is a closed domain subspace of  $X$ , then we have  $A$  and  $B$  be any disjoint  $\pi$ -closed sets of  $X$ . By quasi  $g\zeta^*$ -normal of  $X$ , there exist disjoint  $g\zeta^*$ -open subsets  $U$  and  $V$  of  $X$  such that  $A \subset U$  and  $B \subset V$ . By the **Lemma 4.12**, we obtain  $U \cap M$  and  $V \cap M$  are disjoint  $g\zeta^*$ -open sets in  $M$  such that  $A \subset U \cap M$  and  $B \subset V \cap M$ . Hence,  $M$  is quasi  $g\zeta^*$ -normal subspace.

Since every closed and open (clopen) subset is a closed domain, then we have the following corollary.

**4.14 Corollary.** Quasi  $g\zeta^*$ -normality is a hereditary with respect to clopen subspaces.

The following result is useful for giving some other characterizations of quasi  $g\zeta^*$ -normal spaces.

**4.15 Theorem.** For a space  $X$ , the following are equivalent:

- (a)  $X$  is quasi  $g\zeta^*$ -normal.

- (b) For any disjoint  $\pi$ -closed sets  $H$  and  $K$ , there exist disjoint  $gg\zeta^*$ -open sets  $U$  and  $V$  such that  $H \subset U$  and  $K \subset V$
- (c) For any disjoint  $\pi$ -closed sets  $H$  and  $K$ , there exist disjoint  $\pi gg\zeta^*$ -open sets  $U$  and  $V$  such that  $H \subset U$  and  $K \subset V$ .
- (d) For any  $\pi$ -closed set  $H$  and any  $\pi$ -open set  $V$  containing  $H$ , there exists a  $gg\zeta^*$ -open set  $U$  of  $X$  such that  $H \subset U \subset g\zeta^*\text{-cl}(U) \subset V$ .
- (e) For any  $\pi$ -closed set  $H$  and any  $\pi$ -open set  $V$  containing  $H$ , there exists a  $\pi gg\zeta^*$ -open set  $U$  of  $X$  such that  $H \subset U \subset g\zeta^*\text{-cl}(U) \subset V$ .

**Proof.** (a)  $\Rightarrow$  (b), (b)  $\Rightarrow$  (c), (c)  $\Rightarrow$  (d), (d)  $\Rightarrow$  (e) and (e)  $\Rightarrow$  (a).

(a)  $\Rightarrow$  (b). Let  $X$  be quasi  $g\zeta^*$ -normal space. Let  $H, K$  be disjoint  $\pi$ -closed sets of  $X$ . By assumption, there exist disjoint  $g\zeta^*$ -open sets  $U, V$  such that  $H \subset U$  and  $K \subset V$ . Since every  $g\zeta^*$ -open set is  $gg\zeta^*$ -open,  $U$  and  $V$  are  $gg\zeta^*$ -open sets such that  $H \subset U$  and  $K \subset V$ .

(b)  $\Rightarrow$  (c). Let  $H, K$  be two disjoint  $\pi$ -closed sets. By assumption, there exist disjoint  $gg\zeta^*$ -open sets  $U$  and  $V$  such that  $H \subset U$  and  $K \subset V$ . Since  $gg\zeta^*$ -open set is  $\pi gg\zeta^*$ -open,  $U$  and  $V$  are  $\pi gg\zeta^*$ -open sets such that  $H \subset U$  and  $K \subset V$ .

(c)  $\Rightarrow$  (d). Let  $H$  be any  $\pi$ -closed set and  $V$  be any  $\pi$ -open set containing  $H$ . By assumption, there exist disjoint  $\pi gg\zeta^*$ -open sets  $U$  and  $W$  such that  $H \subset U$  and  $X - V \subset W$ . By **Theorem 3.3**, we get  $X - V \subset g\zeta^*\text{-int}(W)$  and  $g\zeta^*\text{-cl}(U) \cap g\zeta^*\text{-int}(W) = \emptyset$ . Hence  $H \subset U \subset g\zeta^*\text{-cl}(U) \subset X - g\zeta^*\text{-int}(W) \subset V$ .

(d)  $\Rightarrow$  (e). Let  $H$  be any  $\pi$ -closed set and  $V$  be any  $\pi$ -open set containing  $H$ . By assumption, there exist  $gg\zeta^*$ -open set  $U$  of  $X$  such that  $H \subset U \subset g\zeta^*\text{-cl}(U) \subset V$ . Since, every  $gg\zeta^*$ -open set is  $\pi gg\zeta^*$ -open, there exists  $\pi gg\zeta^*$ -open sets  $U$  of  $X$  such that  $H \subset U \subset g\zeta^*\text{-cl}(U) \subset V$ .

(e)  $\Rightarrow$  (a). Let  $H, K$  be any two disjoint  $\pi$ -closed sets of  $X$ . Then  $H \subset X - K$  and  $X - K$  is  $\pi$ -open. By assumption, there exists  $\pi gg\zeta^*$ -open set  $G$  of  $X$  such that  $H \subset G \subset g\zeta^*\text{-cl}(G) \subset X - K$ . Put  $U = g\zeta^*\text{-int}(G)$ ,  $V = X - g\zeta^*\text{-cl}(G)$ . Then  $U$  and  $V$  are disjoint  $g\zeta^*$ -open sets of  $X$  such that  $H \subset U$  and  $K \subset V$ .

## 5. Preservation Theorems

**5.1 Definition.** A function  $f : X \rightarrow Y$  is said to be

- (a)  **$g\zeta^*$ -closed [8]** (resp.  **$\pi gg\zeta^*$ -closed**) if  $f(F)$  is  $g\zeta^*$ -closed (resp.  $\pi gg\zeta^*$ -closed) in  $Y$  for every closed set  $F$  of  $X$ .
- (b) **rc-preserving [14]** (resp. **almost closed [19], almost  $g\zeta^*$ -closed, almost  $\pi gg\zeta^*$ -closed**) if  $f(F)$  is regular closed (resp. closed,  $g\zeta^*$ -closed,  $\pi gg\zeta^*$ -closed) in  $Y$  for every  $F \in RC(X)$ .
- (c)  **$\pi$ -continuous [4]** (resp. **almost  $\pi$ -continuous [4]**) if  $f^{-1}(F)$  is  $\pi$ -closed in  $X$  for every closed (resp. regular closed) set  $F$  of  $Y$ .
- (d) **almost continuous [19]** if  $f^{-1}(V)$  is open in  $X$  for every regular open set  $V$  of  $Y$ .
- (e)  **$\pi gg\zeta^*$ -continuous** (resp. **almost  $\pi gg\zeta^*$ -continuous**) if  $f^{-1}(F)$  is  $\pi gg\zeta^*$ -closed in  $X$  for every closed (resp. regular closed) set  $F$  of  $Y$ .

**5.2 Theorem.** If  $f : X \rightarrow Y$  is an almost  $\pi$ -continuous and  $\pi g g \zeta^*$ -closed function, then  $f(A)$  is  $\pi g g \zeta^*$ -closed in  $Y$  for every  $\pi g g \zeta^*$ -closed set  $A$  of  $X$ .

**Proof.** Let  $A$  be any  $\pi g g \zeta^*$ -closed set of  $X$  and  $V$  be any  $\pi$ -open set of  $Y$  containing  $f(A)$ . Since  $f$  is almost  $\pi$ -continuous,  $f^{-1}(V)$  is  $\pi$ -open in  $X$  and  $A \subset f^{-1}(V)$ . Therefore, we have  $g \zeta^* \text{-cl}(A) \subset f^{-1}(V)$  and hence  $f(g \zeta^* \text{-cl}(A)) \subset V$ . Since  $f$  is  $\pi g g \zeta^*$ -closed,  $f(g \zeta^* \text{-cl}(A))$  is  $\pi g g \zeta^*$ -closed in  $Y$  and hence we obtain  $g \zeta^* \text{-cl}(f(A)) \subset g \zeta^* \text{-cl}(f(g \zeta^* \text{-cl}(A))) \subset V$ . Hence  $f(A)$  is  $\pi g g \zeta^*$ -closed in  $Y$ .

**5.3 Theorem.** A surjection  $f : X \rightarrow Y$  is almost  $\pi g g \zeta^*$ -closed if and only if for each subset  $S$  of  $Y$  and each  $U \in \text{RO}(X)$  containing  $f^{-1}(S)$ , there exists a  $\pi g g \zeta^*$ -open set  $V$  of  $Y$  such that  $S \subset V$  and  $f^{-1}(V) \subset U$ .

**Proof. Necessity.** Suppose that  $f$  is almost  $\pi g g \zeta^*$ -closed. Let  $S$  be a subset of  $Y$  and  $U \in \text{RO}(X)$  containing  $f^{-1}(S)$ . If  $V = Y - f(X - U)$ , then  $V$  is a  $\pi g g \zeta^*$ -open set of  $Y$  such that  $S \subset V$  and  $f^{-1}(V) \subset U$ .

**Sufficiency.** Let  $F$  be any regular closed set of  $X$ . Then  $f^{-1}(Y - f(F)) \subset (X - F)$  and  $(X - F) \in \text{RO}(X)$ . There exists a  $\pi g g \zeta^*$ -open set  $V$  of  $Y$  such that  $Y - f(F) \subset V$  and  $f^{-1}(V) \subset (X - F)$ . Therefore, we have  $f(F) \supset (Y - V)$  and  $F \subset X - f^{-1}(V) \subset f^{-1}(Y - V)$ . Hence we obtain  $f(F) = Y - V$  and  $f(F)$  is  $\pi g g \zeta^*$ -closed in  $Y$ , which shows that  $f$  is almost  $\pi g g \zeta^*$ -closed.

**5.4 Theorem.** If  $f : X \rightarrow Y$  is an almost  $\pi g g \zeta^*$ -continuous, rc-preserving injection and  $Y$  is quasi  $g \zeta^*$ -normal, then  $X$  is quasi  $g \zeta^*$ -normal.

**Proof.** Let  $A$  and  $B$  be any disjoint  $\pi$ -closed sets of  $X$ . Since  $f$  is an rc-preserving injection,  $f(A)$  and  $f(B)$  are disjoint  $\pi$ -closed sets of  $Y$ . Since  $Y$  is quasi  $g \zeta^*$ -normal, there exist disjoint  $g \zeta^*$ -open sets  $U$  and  $V$  of  $Y$  such that  $f(A) \subset U$  and  $f(B) \subset V$ .

Now if  $G = \text{int}(\text{cl}(U))$  and  $H = \text{int}(\text{cl}(V))$ . Then  $G$  and  $H$  are regular open sets such that  $f(A) \subset G$  and  $f(B) \subset H$ . Since  $f$  is almost  $\pi g g \zeta^*$ -continuous,  $f^{-1}(G)$  and  $f^{-1}(H)$  are disjoint  $\pi g g \zeta^*$ -open sets containing  $A$  and  $B$ , respectively. It follows from **Theorem 4.15**, that  $X$  is quasi  $g \zeta^*$ -normal.

**5.5 Theorem.** If  $f : X \rightarrow Y$  is a  $\pi$ -continuous, almost  $g \zeta^*$ -closed surjection and  $X$  is quasi  $g \zeta^*$ -normal space then  $Y$  is  $g \zeta^*$ -normal.

**Proof.** Let  $A$  and  $B$  be any two disjoint closed sets of  $Y$ . Then  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint  $\pi$ -closed sets of  $X$ . Since  $X$  is quasi  $g \zeta^*$ -normal, there exist disjoint  $g \zeta^*$ -open sets  $U$  and  $V$  such that  $f^{-1}(A) \subset U$  and  $f^{-1}(B) \subset V$ .

Let  $G = \text{int}(\text{cl}(U))$  and  $H = \text{int}(\text{cl}(V))$ . Then  $G$  and  $H$  are disjoint regular open sets of  $X$  such that  $f^{-1}(A) \subset G$  and  $f^{-1}(B) \subset H$ . Now, we set  $K = Y - f(X - G)$  and  $L = Y - f(X - H)$ . Then  $K$  and  $L$  are  $g \zeta^*$ -open sets of  $Y$  such that  $A \subset K$ ,  $B \subset L$ ,  $f^{-1}(K) \subset G$  and  $f^{-1}(L) \subset H$ . Since  $G$  and  $H$  are disjoint, so are  $K$  and  $L$ . Since  $K$  and  $L$  are  $g \zeta^*$ -open and we obtain  $A \subset g \zeta^* \text{-int}(K)$ ,  $B \subset g \zeta^* \text{-int}(L)$  and  $g \zeta^* \text{-int}(K) \cap g \zeta^* \text{-int}(L) = \emptyset$ . Therefore,  $Y$  is  $g \zeta^*$ -normal.

**5.6 Theorem.** Let  $f : X \rightarrow Y$  be an almost  $\pi$ -continuous and almost  $\pi g g \zeta^*$ -closed surjection. If  $X$  is quasi  $g \zeta^*$ -normal space then  $Y$  is quasi  $g \zeta^*$ -normal.

**Proof.** Let  $A$  and  $B$  be any disjoint  $\pi$ -closed sets of  $Y$ . Since  $f$  is almost  $\pi$ -continuous,  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint  $\pi$ -closed sets of  $X$ . Since  $X$  is quasi  $g\zeta^*$ -normal, there exist disjoint  $g\zeta^*$ -open sets  $U$  and  $V$  of  $X$  such that  $f^{-1}(A) \subset U$  and  $f^{-1}(B) \subset V$ .

Put  $G = \text{int}(\text{cl}(U))$  and  $H = \text{int}(\text{cl}(V))$ . Then  $G$  and  $H$  are disjoint regular open sets of  $X$  such that  $f^{-1}(A) \subset G$  and  $f^{-1}(B) \subset H$ . By **Theorem 5.3**, there exist  $\pi g\zeta^*$ -open sets  $K$  and  $L$  of  $Y$  such that  $A \subset K$ ,  $B \subset L$ ,  $f^{-1}(K) \subset G$  and  $f^{-1}(L) \subset H$ . Since  $G$  and  $H$  are disjoint, so are  $K$  and  $L$  by **Theorem 3.3**,  $A \subset g\zeta^*\text{-int}(K)$ ,  $B \subset g\zeta^*\text{-int}(L)$  and  $g\zeta^*\text{-int}(K) \cap g\zeta^*\text{-int}(L) = \emptyset$ . Therefore,  $Y$  is quasi  $g\zeta^*$ -normal.

**5.7 Corollary.** If  $f : X \rightarrow Y$  is an almost continuous and almost closed surjection and  $X$  is a normal space, then  $Y$  is quasi  $g\zeta^*$ -normal.

**Proof.** Since every almost closed function is almost  $\pi g\zeta^*$ -closed. Therefore, by **Theorem 5.6**,  $Y$  is quasi  $g\zeta^*$ -normal.
