## **ABSTRACT**

The solution studies the proton-ligand stability constant  $pK$  and metal-ligand stability constants  $\log k$  of binary (1 : 1) complexes of Ni(II), Cu(II) and Zn(II) with substituted Quinoline Pyrimidines drugs have been studied at 0.1M ionic strength in 70 % DMF-water mixture by Bjerrum method as adopted by Calvin and Wilson. It is observed that Ni(II), Cu(II) and Zn(II) metal ions form 1:1 and 1:2 complexes with ligands ( $L_1$  &  $L_2$ ). The data obtained were used to estimate and compare the values of proton-ligand stability constant ( $pK$ ) and metal-ligand stability constants ( $\log k$ ). From estimated data ( $pK$  and  $\log k$ ), the effects of substituents were studied.

**Keywords:** Substituted Quinoline Pyrimidines drugs, stability constant, pH-metry.

## **INTRODUCTION**

Pyrimidine moiety is an important class of nitrogen containing heterocycles [1] and is widely used as a key building block for pharmaceutical agents. Its derivatives exhibit antibacterial, antifungal[2], analgesic[3], calcium antagonist[4], anti-inflammatory[5] and anti-tumor activity[6]. In addition, several marine natural products with interesting biological activities containing pyrimidine core have recently been isolated[7].

Recently, there has been considerable interest in the study of binary and ternary complexes by pH-metric method[8- 10] using biomolecules (drugs). Drugs have various functional groups present in its structure, which can bind to metal ions present in human body[11]. Metal complexes of drug are found to be more potent than parent drugs[12]. Chemistry of drugs attracts many researchers because of its applications in medicinal chemistry. Interesting results have been reported earlier on complex formation reactions of drug- transition metal ion complexes[13-15]. Coordination compounds play very important role in numerous chemical, biological and biochemical activities e.g. Chlorophyll, a magnesium complex essential for photosynthesis in plants; Haemoglobin, an iron complex, which carries oxygen to living organism cells; Coenzyme-Vitamin B<sub>12</sub>, a cobalt complex which serves as a prosthetic group in metabolic activities of living organisms. The application of coordination chemistry is varied in the field of biological, biochemistry, medicine, agriculture, organometallic chemistry, solid state chemistry, catalysis and molecular receptors and devices. The metal ion complexes as a catalyst are invariably involved in various industrial processes.

Stability constant is well known tool for solution chemist, biochemist, and chemist. In general it help for determination the properties of metal-ligand reactions in water and biological system[16] . In the study of coordination compound in solution, first and foremost requirement is the knowledge of stability constant of complex. Reliable information of stability constant is of great importance in analytical and separation procedure. To remove undesirable and harmful metals from living organism, chelating agents are very much

useful in biological systems. This gives importance to the study of determination of stability constant of metal complexes.

The complexes have been extensively studied in solution as well as in solid state by many workers, due to its remarkable properties and high stability. Though vast amount of work has been done on stability constant of metal complexes. Many workers study the effect of transition metal on a stability of complex by pH metrically[17-19]. Also there is a investigation of stability constant of ligand with lanthanide metals[20-23].

In the present work, effect of metal ions such as Ni(II), Cu(II) and Zn(II) on the properties of complexes of substituted Quinoline Pyrimidines in 70% DMF+water mixture at 309K has studied. The ligands used are

**L<sub>1</sub>: 4-(2-Chloro-6-methylquinolin-3-yl)-6-(4-methoxyphenyl)-3,4-dihydropyrimidin-2(1H)-one**

**L<sub>2</sub>: 4-(2-Chloro-6-methylquinolin-3-yl)-6-(4-chlorophenyl)-3,4-dihydropyrimidin-2(1H)-one**

## EXPERIMENTAL SECTION

All chemicals used are of AR grade. The ligands (L<sub>1</sub>) & (L<sub>2</sub>) were synthesized in the laboratory by reported protocol. The stock solutions of the ligand was prepared by dissolving required amount of ligand in a of 70% (DMF+water) mixture.

### Metal ions used (divalent metal ion in nitrates forms)

Ni(II), Cu(II) and Zn(II).

### Stock solution

1M KNO<sub>3</sub> solution, 0.1M HNO<sub>3</sub> solution, 0.1M NaOH and 0.01M Transition metal ions solution are prepared in double distilled water . 0.01 M ligand (L<sub>1</sub> and L<sub>2</sub>) solution in 70% (DMF –water) mixture.

### • Calvin –Bjerrum titration methods

All pH-metric titrations and pH-measurements were carried out with EQUIP-TRONIC DIGITAL pH meter model EQ-610 (accuracy ±0.05 units) with a glass and calomel electrodes assembly. at (36±0.1)<sup>o</sup>c in 70% (DMF-water) mixture and at an inert atmosphere by bubbling nitrogen gas .

**General procedure :**

Types of Titrations

- i) Free acid HNO<sub>3</sub>(0.01 M)
- ii) Free acid HNO<sub>3</sub>(0.01 M) and ligand (20 x 10<sup>-4</sup>M)
- iii) Free acid HNO<sub>3</sub> (0.01 M) and ligand (20 x 10<sup>-4</sup>) and metal ion (4 x 10<sup>-4</sup>M) against standard 0.1N NaOH solution.

The ionic strength of all the solutions was maintained constant 1M by adding appropriate amount of KNO<sub>3</sub> solution. All the titrations were carried out in 70% (DMF-water) mixture and the reading were recorded for each 0.2 ml addition. The graph of volume of alkali added (NaOH) against pH were plotted.

**CALCULATION**

Titration curves are used to estimate the values of  $n_A$  (proton -ligand formation number) which are presented in Table-1 to 2. Formation curve are constructed between  $n_A$  and pH. The pH values at 0.5  $n_A$  represent the pK values (proton-ligand dissociation constants) of respective ligand. Proton ligand dissociation constants (pK) are evaluated and presented in Table-3, which are calculated by half integral and verified by pointwise calculations method.

**RESULTS AND DISCUSSION**

The ligands involved in the present work may be considered as a monobasic acid having only one dissociable H<sup>+</sup> ion from thiolic -SH group and it can therefore, be represented as HL. The dissociating equilibria can be shown as.

By the law of mass action, we have,

$$K = \frac{[H^+][L^-]}{[HL]} \dots\dots\dots (1)$$

where, the quantities in bracket denote the activities of the species at equilibrium.

**Calculation of Proton-Ligand Stability Constant ( $n_A$ )**

The plots between volume of NaOH and pH of the solution were used to determine the proton ligand stability constant (representing the replacement of H<sup>+</sup> ions from functional group of ligand with respect to pH value). The horizontal difference ( $V_2 - V_1$ ) was measured accurately between the titration curves of free acid and acid + ligand. It was used to calculate the formation number  $n_A$  at various pH values and fixed ionic strength  $\mu = 0.1M$  using Irving and Rossotti's equation[1,2]

$$\bar{n}_A = \gamma - \frac{(V_2 - V_1)(N + E^0)}{(V^0 + V_1)T_1^0} \dots\dots\dots (2)$$

where,  $V^0$  is the initial volume of the solution.  $E^0$  and  $TL^0$  are initial concentrations of the mineral acid and ligand respectively.  $V_1$  and  $V_2$  are the volumes of alkali of normality N during the acid and ligand titration at given pH.  $\gamma$  is the replaceable proton from the ligand.

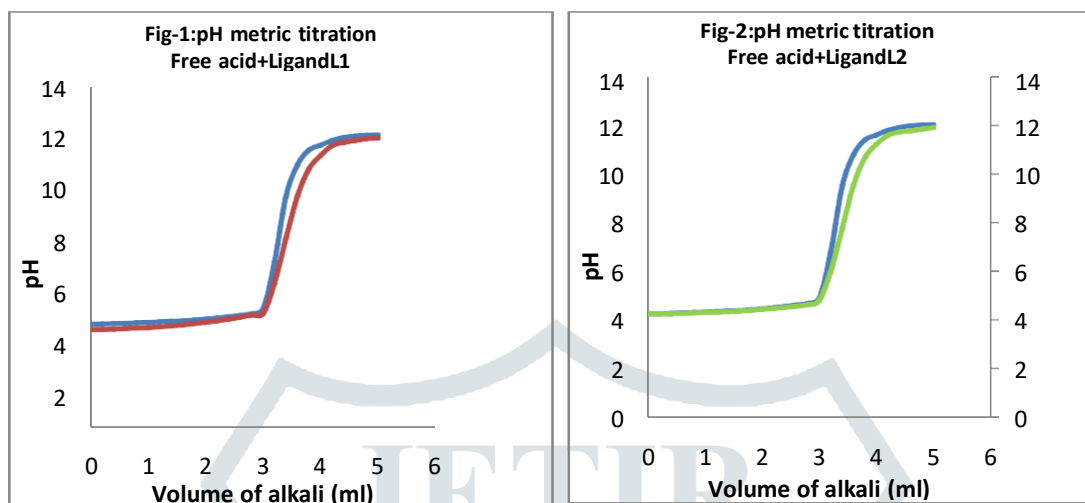

The data of  $n_A$  obtained at various pH along with the horizontal difference for some representative systems are represented in Table 1 to 2.

The metal–ligand formation number ( $\bar{n}$ ) is estimated by Irving-Rossotti's equation.

$$N = \frac{(V_3 - V_2)(N + E^0)}{(V^0 + V_2) n_A T_M^0} \dots\dots\dots(3)$$

where the notations have the same meaning as given in earlier equation. The horizontal difference (V<sub>3</sub>-V<sub>2</sub>) between

the metal complex (A+M+L) and reagent (A+L) curve is used to evaluate the value of n using Irving Rossotti's equation.

	Zn(II)	5.49	4.00	1.37	1.49

## CONCLUSION

From the titration curves, it is observed that the deviation between (acid + ligand) curve and (acid + ligand + metal) curve for all systems started from pH = 4.10 this indicated the commencement of complex formation. Also change in colour from yellow to brown in the pH range from 4.10 to 11.50 during titration showed the complex formation between metal and ligand. The order of pK values of ligands are found to be pK ligand (L<sub>2</sub>) < pK ligand (L<sub>1</sub>). The more pK value of ligand (L<sub>1</sub>) is attributed because (L<sub>2</sub>) has electron withdrawing -Cl group which decrease the activity of ligand to form more stable complex.

From the table 10 it is observed that small difference between log K<sub>1</sub> and logK<sub>2</sub> values not more than 2.5 indicates the simultaneous formation of complex between metal ion and ligand. But in case of Cu(II) difference of stability constant is nearly 2.5 indicated than there is a stepwise formation of complex.

From the table-10 it is observed that, in case of Cu(II) ion there is a simultaneous formation of complex for both ligand L<sub>1</sub> and L<sub>2</sub> and in case of Zn(II) ion there is a stepwise formation of complex with both the ligand. But in case of Ni(II) ion, it shows simultaneous complex formation with Ligand L<sub>1</sub> and Stepwise complex formation with ligand L<sub>2</sub>.
