Abstract

Cognitive radio CR is a software Defined Radio (SDR) that consequently distinguishes the encompassing RF, impetuses and cleverly obliges its working parameters to the framework of system and changes it conduct as needs be. In this article we proposed a new integration approach to sensor nodes with cognitive radio (CR) nodes to route sensor data to sink using licensed channels opportunistically. In many investigations the researchers found inefficient utilizations of spectrum. To solve it cognitive radio network is introduced in order to access the dynamic spectrum. The spectrum sensing issue is one of the most challenging problem in CR systems to get in information of the available frequency bands. In this paper we will study various researches which have been carried out for efficient spectrum management such as spectrum sensing, dynamic spectrum access, channel access and allocation. Moreover, energy harvesting, resource management and energy aware routing schemes are also presented.

Keywords: Cognitive Radio, spectrum sensing, Clustering techniques, Wireless sensor network routing

Introduction

Recently, the wireless sensor network (WSNs) are widely adopted and studied in the field of real-time applications, industries, and academia. The applications of WSNs include several compelling operations such as disaster management, environment monitoring, battlefield surveillance, health care systems, underwater surveillance and many more. Generally, the WSNs follow event-driven mechanism to communicate with other nodes. there may exist a few heterogeneous sensor systems which may attempt to get to the activated occasion which can cause delay and inappropriate data collection. In addition, these systems are typically sent in the blocked off area; in this manner, self-organizing capability and network lifetime are pivotal parts of WSN. According to the WSN architecture, it may consist of hundreds of sensor nodes which are deployed randomly in the monitoring sensor field. Source node and base station are the two components of WSNs for data collection. The source noes transmit the data to the base station with the help of single or multi-hop data transmission scheme. Then, the sink node transmits the data to the desired location with the help of the communication channel to accomplish the monitoring application task. Figure 1 shows a general architecture of WSN.

![Figure 1 WSN Architecture](image)

Generally, the WSNs maneuver in industrial scientific and medical (ISM) frequency band whose frequency is assigned as 2.4GHz by Federal Communications (FCC) regulations. However, the ISM bands are unlicensed...
bands which are also accessible by IEEE 802.11 systems, IEEE 802.15.4 WPAN, wireless microphones, and Bluetooth applications. Immense growth and proliferation of wireless communication have led towards the smooth and reliable communication among multiple devices. Hence, the demand for wireless devices is increasing rapidly with a rate of 30-40% every year. The expanded number of wireless devices operating in the ISM band produces interference in all among unrelated applications in wireless communication. Which are using this band. Moreover, the increased number of wireless devices promotes the spectrum scarcity issues because of the availability of limited resources. Additionally, system throughput depends on the use of the channel [2]. Thus, interference, channel utilization, and spectrum management remain challenging issues in wireless communication.

Cognitive radio: a breakthrough in WSN

Recently, the cognitive radio (CR) scheme has emerged as a promising solution to mitigate the issues of spectrum resource scarcity by improving the utilization of available resources. Cognitive radio network (CRN) architecture comprises of primary and secondary users. Whenever, the PU spectrum is underutilized, the secondary users can access it. This process helps to improve spectrum utilization and mitigate the issue of overcrowding of unlicensed band [3]. In CRNs, SUs are not allowed to create any interference to PUs. Once PU initializes any communication on the same channel where SUs is communicating, SUs must evacuate the channel to maintain the no-interference paradigm. The cognitive radio communication techniques are adopted in various types of existing technologies such as machine to machine networks, WBANs, WSN, etc. The cognitive radio networks enables PHY and MAC layers to dynamically detect the available spectrum and change their parameters to achieve the concurrent wireless communication in the given spectrum band. In this work, we consider cognitive radio sensor network (CRSN) as specific technique due to its huge applications in IoT paradigms.

Unlike the conventional WSNs, the CRSNs operate on licensed band and opportunistically sense the spectrum to achieve the channel state information. Similar to CRN, PUs have direct access to the spectrum whereas SUs are allowed to access the spectrum opportunistically. On the other hand, CRSN adopts the general limitations of conventional WSNs such as energy consumption, and network lifetime. Moreover, the spectrum sensing is also considered as a crucial aspect in implementation of CRSNs. The SS has impact on energy consumption because more number of SUs for sensing will require more energy. Hence, current research progresses are focused on efficient approach for spectrum sensing. Similarly, routing and resource allocation is a challenging task in CRSNs. By taking the advantage of spectrum utilization rule of FCC and advancements of networking technology, the combined wireless sensor network and CR can mitigate the challenging issues such as spectrum utilization, resource allocation, and routing to improve the network efficiency.

Contribution of work

This section presents a brief discussion about recent trends and techniques in the field of WSN, CR, and CRSNs. Spectrum sensing is a most important task of CR which has a significant impact on network lifetime when combined with WSN. Various researches have been carried out for efficient spectrum management such as spectrum sensing, dynamic spectrum access, channel access and allocation. Moreover, energy harvesting, resource management and energy aware routing schemes are also presented.

As discussed in previous section, the more number of sensing node require more energy which can lead towards the degraded network lifetime. Moreover, CSRNs are vulnerable to spectrum sensing data falsification (SSDF) attacks which can degrade the sensing accuracy. In order to overcome these issues, Ren et al. [5] developed decision rule for collaborative spectrum sensing. Later, FastDtec scheme is presented to determine the suitable threshold. Further, the compromised nodes are discarded to maintain the security and energy efficiency of the network.

Game theory based schemes are also adopted for spectrum allocation and management. Zeng et al. [6] used Bertrand game theory model for spectrum sharing in CRSNs. According to this process, the secondary BS obtains the communication condition of secondary network and charges for the required spectrum from
The above discussion concludes that in cognitive radio sensor network and novel approach to improve the overall communication performance is mandatory. A heterogeneous cognitive radio sensor network (HCRSN). A cognitive radio enabled sensor network is deployed where they defined various standard parameters such as node capacity, channel, bandwidth available, and bandwidth consumption by each node, power requirements, number of licensed and unlicensed users etc.

Clustering is an effective method to manage communications in cognitive radio sensor networks (CRSNs). In this phase, we perform cluster head and cluster member selection based on their bandwidth availability and channel information [15].

### Conclusion and Future work

The above table (table 2) includes the throughput, postpone time, packet drop to enhance the general overall performance of cognitive radio. If the convention time is included at every step with proper acknowledgement then the quality may be improved further. It is required to focus on the cognitive radio sensor network and introduce a novel approach to improve the overall communication performance. A novel
useful resource allocation and spectrum sensing version with interference cancellation and cooperative routing scheme to enhance the throughput must be evolved. Fault Tolerance is the maximum tough problem in CR-WSN. The protocols designed for cognitive radio do not have the capability to tolerate fault. This influences the overall performance of the wi-fi sensor community. CRN is excessive failure susceptible because of the node mobility and primary consumer (PU) interference. Therefore, a robust routing protocol to address failure at some point of data transmission in CRN is required with some hybrid technology.
