ABSTRACT: *Virtual learning environment. Are widely used in education and across many sectors to provide educational content and improve communication. This paper details the results of an internet questionnaire of 248 2nd students at an English seventh college on their usage of online learning environments. The survey looked into to the impact of using the school's Leon learning, and it has been based on three survey questions: whether using a VLE has a positive impact on student achievement; whether using a VLE in learning and teaching helps students develop independent learning; and whether using a VLE increases students' incentive to learn. According to the statistically significant findings, using Moodle better learning and motivation to learn, as stated by the participating students. Teachers will be interested in the findings because they indicate out areas where they might focus their efforts in order to encourage the use of VLEs to improve the quality of learning.*

KEYWORDS: *Virtual learning environments; student view / voice; motivation; independent learning.*

1. INTRODUCTION

An Online Learning is a web-based computer system that uses tools and activities to enhance teaching and learning easier. Students using a VLE may be assigned the task to do in classroom or at their own pace, time, and place, and they can engage in synchronous and asynchronous discussions to further their knowledge. The usage of a Digital Learning Environment. Was shown to improve student achievement, promote independent learning, and enhance students' motivation to study[1]. This article outlines a research that took place in a particular setting, an English comprehensive school college. Which tested hypotheses about these claims in a positivistic way. This study offers a glimpse of students' views on the usage of the VLE and its effect on student learning, as well as instructor and parent educator recommendations[2].

1.1. A general view of virtual space and learning:

The idea and phenomenon of virtual space has changed greatly from its inception in. The advent of fast and cheap Internet connections and computers, tightly linked with computing and data communication technology, has enabled virtual space to just be available not only in computer labs, but also in homes, universities, and businesses. The rapid development of personal computing and Internet technology has greatly expanded and varied virtual satellite's usage, uses, and usefulness. In the areas of leisure, commerce, cultural heritage, and education, there are numerous instances of Internet-based online environments which are well characteristics. According to one source, World of Warcraft has over 10 million users. On August. Million people accessed the popular Fb application Farmville.

As according Gartner by the end of percent of any and all active Internet users would have a presence online. Virtual space is used in business for selling, advertising, and market analysis. Archaeologists, art historians, and historians are also using virtual reality to recreate and display pieces of art, crafts, and historical settings. In education, there is indeed a similar trend of greater and more diverse use of virtual space. That since 1980s, when virtual space was first used to support learning, it has been a fairly common element in education. There are numerous claimed benefits of using virtual space in schooling. Three-dimensional virtual environment, for example, is often seen as a suitable platform for distant education. This is owing to the many available communicative modalities. And thus the higher possibility for cooperation in the learning space: teachers and students, represented by avatars, may engage via chat, voice, and nonverbal signals such as avatar placement and gestures[1].

1.2. Physical space and learning:

Despite the fact that online world has become more prevalent in education, the interconnections between virtual space characteristics such as light, color, and acoustic and learning are largely unexplored. However,

numerous research has looked at how the actual learning environment influences memory. Two conclusions may be drawn from these investigations. To begin with, it is intriguing to move the field of research from the physical to the virtual world. Second, study into the connection between physical learning space and cognition may potentially improve such investigations[3]. The effects of acoustic on learning have been thoroughly investigated in fields such as cognitive science, and it is well accepted as excessive noise has an influence upon memory, learning, and reading. Furthermore, research have shown repeated bursts of noise may lead to significant teaching time losses.

Another well however fiercely disputed aspect of the physical learning environment was lighting. Both boys. And girls' moods, long-term memory, and issue abilities are affected by lighting, according to Knees. Lighting has a significant effect on overall academic performances, well. Being, and health, according to Higgins ET eland Woolmer ET al. Additionally, research into the impact of virtual and physical space on learning faces similar difficulties. Lighting, room size and layout, color, interior spaces, and acoustics are all factors which influence learning space, both real and virtual. Despite the fact that there is widespread agreement that learning space does have a significant impact on learning, the scientific issue of how to conduct individual assessments of space characteristics is often seen as one of the major challenges. Another issue is how to include contextual variables in research of space and learning, such as personal preferences, gender, age, and culturally and socioeconomically elements[4].

1.3. *A socio-cultural constructivist view of virtual space:*

The insightfulness of virtual space. The interrelationships between space, society, culture, economy, and politics. Was the subject of many studies? Nothing you see on our computer displays is factual or given, as according Taylor. Code is written, images were drawn, sound is recorded, as well as the user actions are the result of deliberate or unconscious design decisions. Even virtual spaces that offer the user a lot of flexibility to create objects, move, and interact are advanced in certain ways[2]. Software development and design, in this perspective, are activities that carve societal norms and values into virtual space, affecting individual users, user groups, and the modes of communication available to them. Clark wrote a story cultural study of how nature is represented in Second Life in a similar vein.

In essence, Clark's results are identical to Taylor's: nature in Second Life is an aggregation of images, meanings, and aesthetic derived from dominant anthropocentric and mainly Western notions of nature. Numerous studies have revealed the cultural, ideological, and political bias of what seem to be neutral and objective virtual spaces. Three-dimensional virtual worlds are often portrayed and sold as exotic travel destinations, according to Book. As a result, the virtual space is intended to suit the user/tourist via the widespread the use travel and tourism metaphors such as "postcard" landscapes and ever, present leisure, play, and entertainment possibilities. Zoo Tycoon, a video game in which the user is placed in charge of a zoo, represents a commercial perspective of the natural world, according to Opel and Smith. Animals are commercialized and regarded as a form of entertainment and profit. The game's goals are monetary gain and human expansion[5].

1.4. *Virtual space, pedagogy, and learning task design:*

Virtual space and teaching interactions have also been investigated from the perspectives of learning task design as well as practical and theoretical pedagogy. These studies have taken one of three places: To begin with, the growing use of virtual world in education requires the creation of a practical and theoretical online pedagogy. In other words, computational models invalidates the "just doing what you did before" approach. Pedagogy established for a conventional, physical school environment must be rethought before it can be effectively applied to virtual education. Second, everybody agrees that each virtual space is its own lesson plan. This means that the design of individual learning tasks must take into account both advantages and disadvantages of the virtual classroom in which they will be performed out. In a similar manner, Bayne. discovered that now the ambiguity of three. Dimensional digital universe may be utilized to generate intriguing issues about ontology and being in higher education. As according Sheehy, instructional

applications of virtual learning spaces, when combined with a well. Grounded pedagogic approach, have the potential to significantly improve inclusive learning. Virtual space, in example, may offer access to real experiences of the world which are otherwise unavailable to certain students owing to distance, budget restrictions, or handicap[6].

1.5. *Architecture and virtual space:*

A number of scholars have used the idea that building is a social object in their study on the interaction between virtual space and learning. Architectural design, in this perspective, has a direct effect on learning because it structures the pattern of founder between individuals and provides opportunities for interaction. Multiple studies in this field have come to remarkably similar findings on the main educational advantages of a well-designed virtual learning environment. In other phrases, a virtual space designed to accommodate a specific learning activity. Such as a teahouse for informal knowledge. Exchange between school mates or a traditional classroom for lectures. May have beneficial influence on student if it is compatible with the educational activity that takes place. In contrast, a virtual learning environment that is unsuitable for such a particular activity may have negative consequences. Many scholars have begun to investigate the impact of virtual space architecture on learning, as we have shown. Despite this, Delagarno and Lee. Found in their literature review of the affordances of three. Dimensional virtual space that best. Practice design principles for online educational space, as well as the education learning value of design and architecture, need further study[7].

1.6. *Educational Multimedia Applications:*

For all computing platforms, there are a range of educational multimedia apps. Similarly, the complexity of audiovisual applications determines the hardware compatibility for online learning. As according Babied et althea supply of minicomputers for students and staff is a major item of expenditure for academic institutions, and one that they are unlikely to repeat every two or three years. As a consequence, computer programmers should think very carefully about which multimedia components to include in programs but only include those that are useful. It is critical to assess the accessible multimedia goods, particularly when they include web - based learning systems as well as the efficacy of educational resources. Furthermore, this study proves that the effectiveness using multimedia apps is reliant on a thorough assessment that takes into account a variety of needs involving school community interactions.

Provided light on the effectiveness of using various multimedia forms when dealing with learners because one learner may show cognitive pleasure in one format while the other one prefers other. Furthermore, while taking web based learning courses, the author discussed the significance of women in preferring certain multimedia formats. Chen and Wang, on either hand, proposed a method for assessing a learner's engagement with different multimedia presentation techniques by collecting and analyzing the learners' emotional expressions. The study of these emotional expressions may provide a fair indication of their happiness and performance. Furthermore, the authors discovered a clear variation in the resulting emotional expressions of learners depending on their gender while using various multimedia presentation methods! Female pupils, they claim, are more readily influenced by a variety multimedia than students.

2. DISCUSSION

Research skills can be taught via virtual learning. Learners know how to locate sources, assess their credibility, and appropriately integrate them into their writing. They may create a toolkit for ongoing content creation. Virtual learning also trains pupils how to adjust and resolve issues on their own. Learners may take their courses from everywhere at any time using web and mobile applications. Virtual classrooms, mail apps, chat forums, wikis, blogs, and scoreboards are all collaborative team elements. Gamified teaching and classroom methods are two instances of innovative lesson delivery. ELearning is, at its core, about learning that occurs outside of the classroom, or bringing whatever occurs outside the classroom into the classroom. As a consequence, we're considering the online world as a means of linking kids who may be physically

present at a classroom with their learning that is occurring elsewhere. ELearning, in particular, delivers instruction to students through computer software, the Internet, or both[8]. Instead, the instructor interacts with the student via online media such as online video, online forums, e-mail, and text messaging. When we use "virtual" in ordinary speech, we usually mean "online," as in "via a computer or device." It's a term used to describe an encounter that doesn't take place in the physical space[9].

3. CONCLUSION

The VLE has a little influence on pupils' academic success in Geotechnics 3 but a considerable impact on their success in the Design Project in the final year of the BEng Civil Engineering School at Boston University, according to the research. The both Spearman's and Pearson's Correlation indicate that VLE usage and academic performance in Geotechnics 3 had insignificant relationships, with a minor positive association with the Design Project. Although the research did not explicitly investigate the question of the most used resource, "resource view" was by far the most frequent action taken by students accessing the VLE. The forums were much less often utilized, but this may be due to a lack of knowledge rather than a lack of usefulness. Both students interviewed were enthusiastic about the concept of forums and felt they might be a helpful tool. They also said that alternative media was not used in the display of materials submitted to the VLE in any of the original study modules. It's possible that if professors were encouraged to provide a broader variety of materials for the VLE and utilize the forum to respond to students' queries, the VLE might be used to its greatest potential and help students achieve their desired learning objectives. The comparison between the two courses with different topic matter and assessment is a limitation of this study. Future study could compare more comparable modules, isolating the impact of VLE usage and eliminating other confounding variables, based to one suggestion[10].
