Iterated function system based image compression algorithm using Discrete Cosine Transform

Dr. Meenakshi ChoudharyUniversity Computer Centre
Dr. Bhimrao Ambedkar University, Agra

Abstract

We analysis that the explosively increasing information of image and video in various storage devices and Internet, the image and video compression technique becomes more and more important. This paper introduces the basic concept of data compression which is applied to modern image and video compression techniques such as DCT, JPEG, MPEG. MPEG-4 and so on.

In this paper we are analyzing various data compression algorithm to perform comparative studies of their algorithm. Theproposal of data compression is to decrease the data correlation. Using Discrete Cosine Transform (DCT), the data in instance domain can be transformed into frequency domain. Because of the less sensitivity of human vision in higher frequency, we can compress the image or video data by suppressing its high frequency components that do no change to our eye. Moving pictures such as video are data in three-dimensional space consists of spatial plane and time axis. Therefore, in addition to reducing spatial correlation, we need to reduce the time correlation. We introduce a method called Motion Estimation (ME).

In this method, we get similar part of image in previous or future frames. By a Motion Vector (MV) replace the image in order to reduce time correlation. In this paper, we also commenceMPEG and JPEG standardwhich are the well-known image and video compression standard.

I Introduction

Presently, the dimension of storage medium increases day by day. Even though the mainability of hard disk is about two Terabytes, it is not enough large if we storage a video file without compressing it. Like, if we have a color video file stream, with three 720x480 sized layer, 30 frames per second and 8 bits for each pixel, this equals to near about 30 MB per second. We can only storage a video about 20 seconds long. The main idea of data compressing is reducing the data correlation and replacing them with simpler data form.

Then we will discuss the method that is common used in image/video compression then we will introduce quantization and entropy coding. After reducing data correlation, the amounts of data are not really reduced. We use

quantization and entropy coding to compress the data. The JPEG standard has been widely used in image and photo compression recently.

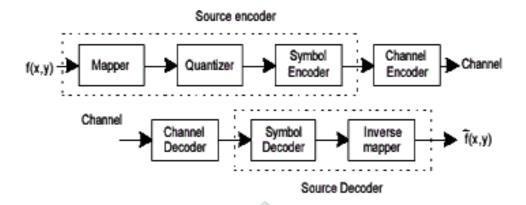

Fig. 1 Encoder and decoder of images

IIFundamentalidea of Data Compression

Impulse of data compression is using less quantity of data to represent theoriginal data without alteration of them. Consider the structure in **Fig. 1**, when encoder receive the goal image, it converts the image into bit stream b. Besides, decoder receives the bit stream and converts it back to the image. If the quantity of bit stream b less than the original image then we call this process *Image Compression Coding*.

Fig. 2 Image compression using JPEG standard

There is an example in **Fig. 2** using JPEG image compression standard. The compression ratio is 15138 / 83261, about 0.1818, around one fifth of theoriginal size. Besides, we can see that the decoded image and the original image are only a little different. Indeed, both images are not perfectly same, means, partsof information are lost during the image compression process.

Hence, the decoder cannot build up the image completely. This type of image compression is known as unreversablecoding or lossy coding. Further, there is another form calledreversible codingthat can perfectly build up the

original image without any misuse and compression ratio of reversible coding is much lesser. For lossy coding, there is a distortion between the original image and the decodedimage. After evaluate the coding efficiency, we need a method to evaluate the degree of distortion. There are two common evaluation tools, which are Mean SquareError(MSE) and Peak Signal to Noise Ratio(PSNR). They are defined as following:

$$MSE = \sqrt{\frac{\sum_{x=0}^{W-1} \sum_{y=0}^{H-1} (f(x,y) - f'(x,y))^{2}}{WH}}$$
 (1)

$$PSNR = 20\log_{10} \frac{255}{MSE}$$
 (2)

Eq. (1), f(x, y) and f'(x, y) stands for the initial image and interpret image, subsequently. The image size is W*H. In Eq. (2), the PSNR formula is commonused for 8-bits image. Note that the larger the PSNR, that smaller the degree of lie.Now, we want to know how and why we can make an image compressed. All over, the nearby pixels in an image have highly correlation to each other. That is why images can be compressed in a high compression ratio. The image coding algorithm consists of reducing correlation between pixels, quantization and entropy coding. The coding algorithm system model is shown in Fig. 3

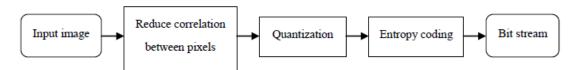

Fig. 3 General constitution of image coding algorithm

III. Discrete Cosine Transform and OrthogonalTransform

III.1 Linear transformation

We have signals in basis form which simply we discuss the case in three dimensional space whereas the case in N dimensional space can be derive easily studied linear transformation in Linear Algebra. It is very useful to represent in the same concept.

We can express any three dimensional vector Bin a column vector $[b_1,b_2,b_3]^t$, where b_1,b_2 and b_3 are values of the three corresponding axes. For a propertransformation matrix \mathbf{X} , we can transform vector \mathbf{b} into another vector \mathbf{a} , we call this a *linear transformation* process. It can be written as:

$$\mathbf{a} = \mathbf{X}\mathbf{b} \tag{3}$$

where band aare vectors \Re^3 space and Xis called a transformationmatrix. Furthermore, consider three linear independent vectors with different direction:

$$v_1 = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}^t, v_2 = \begin{bmatrix} 1 & 0 & 1 \end{bmatrix}^t, v_3 = \begin{bmatrix} 0 & 1 & 1 \end{bmatrix}^t$$
 (4)

Then any vector \Re^3 space can be expressed as the combination of these threeindependent vectors, that is,

$$b = a_1v_1 + a_2v_2 + a_3v_3(5)$$

where a_1, a_2 and a_3 are constants.

III.2 Orthogonal Transformation

Vector in the \Re^3 space define as the combination of three independent vectors. If we choose these three independent vectors such that they are mutually independent, we will have many useful properties and the numerical computation will become easier. In Eq. (5), furthermore, we will have and v_1,v_2 and v_3 that satisfy

$$\begin{cases}
\mathbf{v}_{1} \cdot \mathbf{v}_{2} = \mathbf{v}_{2} \cdot \mathbf{v}_{3} = \mathbf{v}_{1} \cdot \mathbf{v}_{3} = 0 \\
\mathbf{v}_{1} \cdot \mathbf{v}_{1} = \left| \mathbf{v}_{1} \right|^{2} = 1 \\
\mathbf{v}_{2} \cdot \mathbf{v}_{2} = \left| \mathbf{v}_{2} \right|^{2} = 1 \\
\mathbf{v}_{3} \cdot \mathbf{v}_{3} = \left| \mathbf{v}_{3} \right|^{2} = 1
\end{cases}$$
(6)

From Eq. (5) and Eq. (6), a_1,a_2 and a_3 can be found by

$$a_1 = b. v_1, a_2 = b. v_2, a_3 = b. v_3$$
 (7)

We find that it is easy to obtain a_1, a_2 and a_3 just by taking inner product of the vector \mathbf{x} and corresponding vectors.

III. 3 Karhunen-Loeve Transformation

As images have high correlation in a small range, for an image with size $K_1 \times K_2$, we usually divide it into several small blocks with size $N_1 \times N_2$ and we compromise with each block with a transformation that can reduce its pixel correlationseparately. In **Fig. 4**. if we select bigger block size wemay acheive higher compression ratio. Yet, an oversized block size may havelower pixel correlation. There will be aarrangement, in order to do linear transformation to each block in the image, we may scan the pixelin the transformation blocks and transform it into an N dimensional vector.

This canbe seen in **Fig. 5**. The number of total transformation blocks equals to $M = K_1K_2/N_1N_2$ and the number of pixels in a transformation block is $N = N_1N_2$. After horizontal scanning, we have M vectors:

What we want the do is to achieve the optimal orthogonal transform for these vectors in order to reduce the pixel correlation in each transformation blocks. That is, find atransformation matrix **V** such that

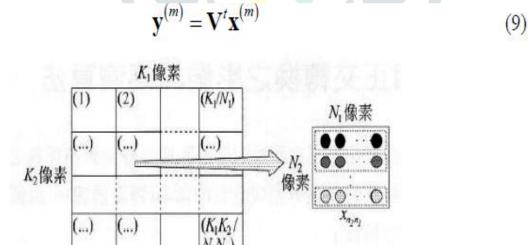

Fig. 4 Image partition and transformation block Ref. [3]

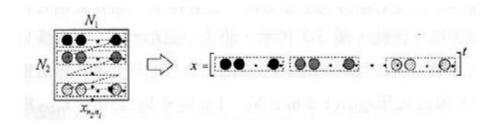

Fig. 5 Transform a transformation block into an N dimensional vector Ref. [3]

Now, consider the covariance of these vector

$$C_{x_{i}x_{j}} = E\left[\left(x_{i}^{(m)} - \overline{x}_{i}^{(m)}\right)\left(x_{j}^{(m)} - \overline{x}_{j}^{(m)}\right)\right] \tag{10}$$

$$C_{y_{i}y_{j}} = E \left[\left(y_{i}^{(m)} - \overline{y}_{i}^{(m)} \right) \left(y_{j}^{(m)} - \overline{y}_{j}^{(m)} \right) \right]$$
(11)

The *i*-th element of $\mathbf{y^{(m)}}$ can be written as

$$y_i^{(m)} = \sum_{n=1}^N v_{ni} x_n^{(m)}$$
 (12)

Then the mean of $y^{(m)}$ is

$$\overline{y}_{i}^{(m)} = E \left[\sum_{n=1}^{N} v_{ni} x_{n}^{(m)} \right] = \sum_{n=1}^{N} v_{ni} E \left[x_{n}^{(m)} \right] = \sum_{n=1}^{N} v_{ni} \overline{x}_{n}^{(m)}$$
(13)

For simpleness, we assume each pixel value $x_i^{(m)}$ is subtracted with its mean value, that is, we substitute $x_i^{(m)}$ with $x_i^{(m)}$ - x_i^{-1} (m). Then the means of latest pixel value $x_i^{(m)}$ and $y_i^{(m)}$ change to zero. Thus we can rewrite Eq. (10) and Eq. (11):

$$C_{x_i x_j} = E \left[x_i^{(m)} x_j^{(m)} \right] \tag{14}$$

$$C_{y_i y_j} = E \left[y_i^{(m)} y_j^{(m)} \right] \tag{15}$$

can be written in a matrix form:

$$C_{xx} = \begin{bmatrix} E \left[x_1^{(m)} x_1^{(m)} \right] & \cdots & E \left[x_1^{(m)} x_N^{(m)} \right] \\ \vdots & \ddots & \vdots \\ E \left[x_N^{(m)} x_1^{(m)} \right] & \cdots & E \left[x_N^{(m)} x_N^{(m)} \right] \end{bmatrix}$$
(16)

$$C_{yy} = \begin{bmatrix} E \left[y_1^{(m)} y_1^{(m)} \right] & \cdots & E \left[y_1^{(m)} y_N^{(m)} \right] \\ \vdots & \ddots & \vdots \\ E \left[y_N^{(m)} y_1^{(m)} \right] & \cdots & E \left[y_N^{(m)} y_N^{(m)} \right] \end{bmatrix}$$
(17)

These are called a covariance matrix. We can easily find that it must be a symmetric matrix. They can be rewritten in a vector form:

$$C_{xx} = E \left[\mathbf{x}^{(m)} \left(\mathbf{x}^{(m)} \right)^t \right] \tag{18}$$

$$C_{yy} = E \left[\mathbf{y}^{(m)} \left(\mathbf{y}^{(m)} \right)^t \right] \tag{19}$$

Moreover, $y^{(m)}$ is obtained by applying linear transformation matrix **V** on $x^{(m)}$:

$$\mathbf{v}^{(m)} = \mathbf{V}^t \mathbf{x}^{(m)} \tag{20}$$

By Eq. (19) and Eq. (20), we find that

$$C_{yy} = E\left[\mathbf{V}^{t}\mathbf{x}^{(m)}\left(\mathbf{V}^{t}\mathbf{x}^{(m)}\right)^{t}\right] = \mathbf{V}^{t}E\left[\mathbf{x}^{(m)}\left(\mathbf{x}^{(m)}\right)^{t}\right]\mathbf{V} = \mathbf{V}^{t}C_{xx}\mathbf{V}$$
 (21)

The purpose is to obtain uncorrelated $\mathbf{y}^{(m)}$. Note that for an uncorrelated $\mathbf{y}^{(m)}$, it has a covariance matrix C_{yy} which is a diagonal matrix. From **Eq.** (21), we find that if C_{yy} is a diagonal matrix then we can regard the right-hand part of this equation is the eigenvalue-eigenvector decomposition of C_{xx} .

The matrix V is composed of the eigenvectors of C_{xx} . Usually, we have it ordered with eigenvectors that have biggercorresponding eigenvalues to smaller ones. This is called the Karhunen-LoeveTransform (KLT).

III.3 Discrete Cosine Transform

Images used likeMPEGor JPEG standard, KLT is not work at this point..Even the optimal orthogonal transformation by applying KLT, it has the following drawbacks:

- 1 Each image has to do the KLT respectively. This makes the computation complexity large.
- **2** In order to decode the encoded image we have to transmit the KLTtransformation matrix to the decoder. It costs another process time andmemory spaces. If we can derive an orthogonal transform that can preserve the optimal property of KLT for all image then we can deal with the problems we mentioned. Then we have the Discrete Cosine Transform (DCT). The forward DCT is defined as

$$F(u,v) = \frac{1}{4}C(u)C(v)\sum_{x=0}^{7}\sum_{y=0}^{7}f(x,y)\cos\left[\frac{\pi(2x+1)u}{16}\right]\cos\left[\frac{\pi(2y+1)v}{16}\right]$$
for $u = 0,..., 7$ and $v = 0,..., 7$
where $C(k) = \begin{cases} 1/\sqrt{2} \text{ for } k = 0\\ 1 \text{ otherwise} \end{cases}$ (22)

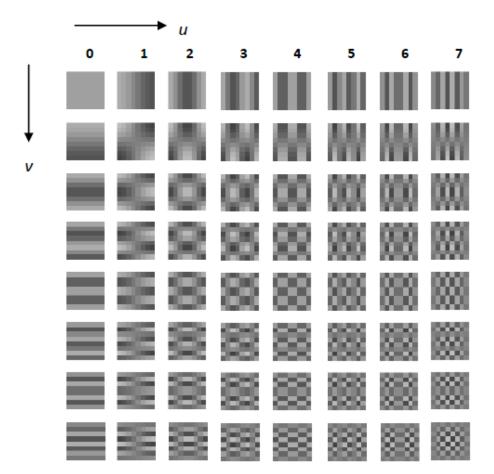

Fig. 6 The 8×8 DCT basis $\omega_{x,y}(u,v)$

And the inverse DCT is defined as the following equation:

$$f(x,y) = \frac{1}{4} \sum_{u=0}^{7} \sum_{v=0}^{7} C(u)C(v)F(u,v) \cos\left[\frac{\pi(2x+1)u}{16}\right] \cos\left[\frac{\pi(2y+1)v}{16}\right]$$
 for $x = 0, ..., 7$ and $y = 0, ..., 7$

The F(u,v) is called the DCT coefficient, and the basis of DCT is:

$$\omega_{x,y}(u,v) = \frac{C(u)C(v)}{4} \cos\left[\frac{\pi(2x+1)u}{16}\right] \cos\left[\frac{\pi(2y+1)v}{16}\right]$$
 (24)

Then we can rewrite the IDCT by Eq. (24):

$$f(x,y) = \sum_{u=0}^{7} \sum_{v=0}^{7} F(u,v)\omega_{x,y}(u,v)$$
 for $x = 0,...,7$ and $y = 0,...,7$ (25)

The 8×8 two dimensional DCT basis is depicted in Fig. 6.

IV Quantization

The transformed 8×8 block in **Fig. 6** consists of 64 DCT coefficients. The firstcoefficient F(0,0) is the DC component and the other 63 coefficients are ACcomponent. The DC component F(0,0) is essentially the sum of the 64 pixels in the input 8×8 pixel block multiplied by the scaling factor (1/4) C(0) C(0) = 1/8as shown in **Eq. (22)** for F(u,v).

99	99	99	99	99	99	99	99
99	99	99	99	99	99	99	99

Fig. 7 Quantization matrix

The next step in the compression process is to quantize the transformed coefficients. Each of the 64 DCT coefficients is uniformly quantized. The 64 quantization step-size parameters for uniform quantization of the 64 DCT coefficients form an 8×8 quantization matrix.

Each element in the quantization matrix is an integer between 1 and 255. Each DCT coefficient F(u,v) is divided by the corresponding quantize step-size parameter Q(u,v) in the quantization matrix and rounded to the nearest integer as:

$$F_{q}(u,v) = Round\left(\frac{F(u,v)}{Q(u,v)}\right)$$
 (26)

The JPEG standard does not define any fixed quantization matrix. It is the prorogate of the user to choose a quantization matrix. There are two quantization matrices provided in Annex K of the JPEG standard for reference, but not requirement. These two quantization matrices are shown in **Fig. 7**.

The process of quantization has the key role in the JPEG compression. It is the process which removes the high frequencies present in the original image. We do this because of the fact that the eye is much more sensitive to lower spatial frequencies than to higher frequencies.

This is done by dividing values at high indexes in the vector (theamplitudes of higher frequencies) with larger values than the values by which are divided the amplitudes of lower frequencies. The bigger values in the quantization table is the bigger error introduced by this lossy process, and the smaller visual quality. Most images have the color varies slow from one pixel to another. Because of this, most images will have a small quantity of high detail to a small amount of high spatial frequencies, and have a lot of image information contained in the low dimentional frequencies.

VAn Example of Image Compression-JPEG Standard

JPEG (Joint Photographic Experts Group) is compression standard for continuous-tone still image, both grayscale and color. This standard is designed to support a wide variety of applications for continuous-tone images. Because of the distinct requirement for each of the applications, the JPEG standard has two basic compression methods. The DCT-based method is specified for lossy compression, and the predictive method is specified for lossless compression.

In this article, we will introduce the lossy compression of JPEG standard. **Fig. 8** shows the block diagram of Baseline JPEG encoder.

V.1 Zig-zag Reordering

Compliting 8×8 DCT and quantization over a block now have 8×8 blocks which denotes the value in frequency domain of the original blocks. Then we have to rearrange the values into one dimensional form in order to encode them.

The DC coefficient is encoded by difference coding. It will be discussed later, term AC are scanned in a Zig-zag manner. The reason for this zig-zag traversing is that we traverse the 8×8 DCT coefficients in the order of increasing the spatial frequencies. So, we get a vector sorted by the criteria of the spatial frequency. In consequence in the quantized vector at high spatial frequencies, we will have a lot of consecutive zeroes. The Zig-zag reordering process is shown in **Fig. 9**.

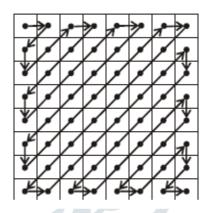

Fig. 9 Zig-Zag reordering matrix

V.2 Zero Run Length Coding of AC Coefficient

The one dimensional quantized vector with a lot of consecutive zeroes, process it by run length coding of the ensuing zeroes. Let's consider the 63 AC coefficients in the original 64 quantized vectors first. For example, we have:

Encode each value except 0, than add the number of successive zeroespreceding that value in front of it. The RLC (Run length Coding) is:

$$(0,57)$$
; $(0,45)$; $(4,23)$; $(1,-30)$; $(0,-16)$; $(2,1)$; EOB

The EOB (End of Block) is a special coded value. If we have reached in a position in the vector from which we have till the end of the vector only zeroes, we'll mark that position with EOB and finish the RLC of the quantized vector,

if the quantized vector not finishes with zeroes (the last element is not 0), we do not add the EOB marker. EOB is equivalent to (0,0), so we have :

$$(0,57)$$
; $(0,45)$; $(4,23)$; $(1,-30)$; $(0,-16)$; $(2,1)$; $(0,0)$

The JPEG Huffman coding makes the restriction that the number of previous 0's to becoded as a 4-bit value, so it can't overpass the value 15 (0xF). So, this example wouldbe coded as:

$$(0,57)$$
; $(15,0)$; $(2,3)$; $(4,2)$; $(15,0)$; $(15,0)$; $(1,895)$; $(0,0)$

(15,0) is a special coded value which indicates that there are 16 consecutive zeroes.

V.3 Difference Coding of DC Coefficient

Because the DC coefficients in the blocks are highly correlated with each other. DC coefficients contain a lot of energy so they usually have much largervalue than AC coefficients. So, we have to reduce the correlation before doing encoding. The JPEG standard encodes the difference between the DCcoefficients. We compute the difference value between adjacent DC values by the following equation:

$$Diff_{i} = DC_{i} - DC_{i-1} \tag{27}$$

Note that the initial DC value is set to zero. Then the difference is Huffman encodedtogether with the encoding of AC coefficients. The difference coding process is shownin **Fig. 10**.

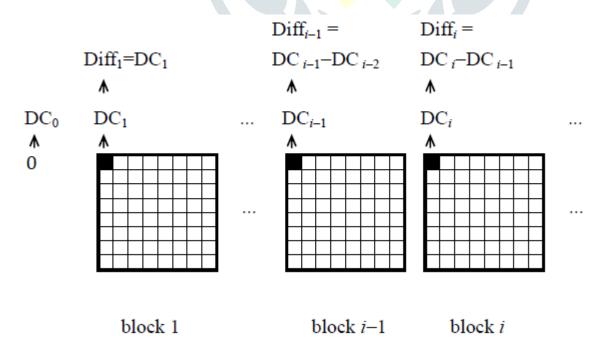

Fig. 10 Difference coding of DC coefficients

Because the Huffman coding is not in the scope of this research, the Huffman codingis not discussed in this paper.

VI Conclusions

We have introduced the basic concepts of image compression and the overview of JPEG standard. Although there is much more details we did not mentioned, the important parts are discussed in this paper.

The JPEG standard has become the mostpopular image format; it still has some properties to improvement. The compression can be higher without block effect by using wavelet-based JPEG 2000 standard.
