<sup>3</sup> Lovely Professional University, Punjab, Punjab Technical University, Punjab, Lovely Professional University, Punjab.

Abstract. In this paper, we study  $r$   $g$ -irresolute and  $r$   $g$ -continuous functions through the idea of  $r$   $g$ -closed sets along with the ideas related to the classes of  $r$   $g$ -compact spaces and  $r$   $g$ -connected spaces.

Keywords:  $r$   $g$ -closed set, continuous map, connectedness and compactness

Mathematics Subject Classification [2000] :54A05, 54C05, 54D05, 54D30

## 1 Introduction

Levine in 1970 developed the concept of  $g$ -closed sets, defined as a set  $X$  ( $X; \tau$ ) is  $g$ -closed if  $cl(X)$  is contained into each open superset of  $X$  [10]. The thought has been used widely as of late by numerous topologist since  $g$ -closed sets remain not just characteristic speculation of closed sets. They likewise proposed a few fundamental characteristics of topological spaces. The investigation of  $g$ -closed sets would give the conceivable usage in PC illustrations [[7]- [9]] and their properties had been observed to be valuable in software engineering and digital topology (see [[6]-[9]], for instance). Due to speculations of pre closed sets,  $gp$ - closed were presented and examined in [14]. The same creators [11] utilized  $gp$ -closed sets to get a few portrayals of prenormal spaces in [12]. This thought was further contemplated in the work of [3],[1], [11] and [13]. Further [15] characterized and concentrated upon the idea of  $gpr$ -closed sets using  $gp$ -closed sets and presented the ideas of preregular  $T_1$  - space and  $rgp$ -continuity. Authors

[5] have proceeded with the investigation of characteristics of  $gpr$ -closed sets and  $gpr$ -continuous functions. As of late, [4] characterized the idea of  $gp$ -closed sets and utilized this thought to get hypothesis for quasi normal spaces. All the more as of late, Bhardwaj et. al. [2] had presented and examined the idea of  $r$   $g$ -closed sets as well as  $r$   $g$ -closed sets. In this paper, we will proceed with the investigation of  $r$   $g$ -closed sets, along with presenting and describing  $r$   $g$ -continuous and  $r$   $g$ -irresolute functions. We also presented the ideas of  $r$   $g$ -compactness and  $r$   $g$ -connectedness, and investigated their conduct under  $r$   $g$ -continuous functions.

## 2 Definition of Regular - Generalized Weakly Closed Function and its Properties

In this section, we consider the functions by involving  $r$ - $\wedge$ -closed sets and present a new class of regular  $\wedge$ -generalized weakly (briefly  $r$ - $\wedge$ -continuous) continuous mapping, concept of quasi  $r$ - $\wedge$ -open functions and discuss their characterization and basic properties.

Definition 1. A function  $f : (A; \tau) \rightarrow (B; \sigma)$  known as regular  $\wedge$ -generalized closed (in brief  $r$ - $\wedge$ -closed) map if  $F$  closed set of space  $(A; \tau)$ ,  $f(F)$  is regular  $\wedge$ -generalized closed set in space  $(B; \sigma)$ .

Theorem 1. Each  $r$ -closed map is a  $r$ - $\wedge$ -generalized closed map.

Proof. Consider  $f : (A; \tau) \rightarrow (B; \sigma)$  is  $r$ -closed map i.e.  $f(X)$  is  $r$ -closed set for each closed set  $X$  of  $A$ . Since each  $r$ -closed set is  $r$ - $\wedge$ -closed set so  $f(X)$  also satisfies the definition of  $r$ - $\wedge$ -closed set. Thus we have  $f(X)$  is  $r$ - $\wedge$ -closed set for each closed set  $X$  of  $A$ . Hence  $f$  is  $r$ - $\wedge$ -closed. The opposite of this hypothesis does not remain constant as appeared by taking after case.

Example 1. Let us consider  $A = \{f, m, n\}$  and topologies  $\tau = \{f, m, n, \emptyset, A\}$ ,  $\sigma = \{f, m, n, \emptyset, A\}$ . Here we have collections of  $r$ - $\wedge$ -closed sets

in  $(A; \tau)$  and  $(A; \sigma)$  are  $\{f, m, n, \emptyset, A\}$  and  $\{f, m, n, \emptyset, A\}$  and collection of  $(A; \tau)$   $r$ -closed sets is  $\{f, m, n, \emptyset, A\}$ . Define  $f : (A; \tau) \rightarrow (B; \sigma)$  by  $f(f) = m$ ,  $f(m) = n$ ,  $f(n) = f$ . Now  $\{f, m\}$  is  $r$ - $\wedge$ -closed set but  $f(\{f, m\}) = \{m, n\}$  is not  $r$ -closed. Thus  $f$  is  $r$ - $\wedge$ -closed map but not  $r$ -closed map.

Theorem 2. If  $f : A \rightarrow B$  is a closed map and  $g : B \rightarrow C$ , a  $r$ - $\wedge$ -closed map then  $g \circ f : A \rightarrow C$  is  $r$ - $\wedge$ -closed.

Proof. Consider  $H$  be closed and  $g(H)$  be  $r$ - $\wedge$ -closed. To show  $f^{-1}(g(H))$  is  $r$ - $\wedge$ -closed. Suppose a closed set  $H$  from space  $A$ . Then by definition of closed map  $f(H)$  is closed and  $g(f(H)) = g(H)$  is  $r$ - $\wedge$ -closed as  $g$  is  $r$ - $\wedge$ -closed. Thus,  $f^{-1}(g(H))$  is  $r$ - $\wedge$ -closed.

## 3 $r$ - $\wedge$ -continuous and $r$ - $\wedge$ -irresolute functions

Definition 2. A function  $f : (A; \tau) \rightarrow (B; \sigma)$  known as  $r$ - $\wedge$ -continuous if  $f^{-1}(V)$  is  $r$ - $\wedge$ -closed in space  $(A; \tau)$  for each closed set  $V$  in space  $(B; \sigma)$ .

Example 2. Let  $A = \{f, m, n\}$ ,  $\tau = \{f, m, n, \emptyset, A\}$  also  $B = \{f, m, n, \emptyset, A\}$ ,  $\sigma = \{f, m, n, \emptyset, A\}$ .

$f : (A; \tau) \rightarrow (B; \sigma)$  with  $f^{-1}(l) = l$  and  $f^{-1}(m) = n$ . Since every subset of  $(A; \tau)$  is  $r$ - $g$ -closed thus  $f$  is  $r$ - $g$ -continuous.

Definition 3. A function  $f : (A; \tau) \rightarrow (B; \sigma)$  known as  $r$ - $g$ -irresolute if  $f^{-1}(V)$  is  $r$ - $g$ -closed within space  $(A; \tau)$  for  $r$ - $g$ -closed set  $V$  in  $(B; \sigma)$ .

^  
On r g-continuous functions in topological spaces 3

Example 3. Let  $A = \{m, ng, f\}$ ;  $A_1 = \{f\}$ ;  $A_2 = \{m, ng\}$  and  $f : A \rightarrow A_1 \cup A_2$  defined by  $f(m) = m$  and  $f(ng) = f$ . At that point

inverse image of each r g-closed set is r g-closed under  $f$ . Therefore,  $f$  is r g-irresolute.

Theorem 3. Every r g-irresolute function is r g-continuous.

Proof. Let  $f : (A; \tau) \rightarrow (B; \sigma)$  be r g-irresolute function, i.e.  $f^{-1}(V)$  is r g-closed in  $(A; \tau)$  for each r g-closed set  $V$  in  $(B; \sigma)$ . Now since, each closed set is r g-closed set. Thus  $f^{-1}(V)$  is r g-closed in  $(A; \tau)$  for each closed set  $V$  in  $(B; \sigma)$ .

Theorem 4. If  $f : (A; \tau) \rightarrow (B; \sigma)$  and  $g : (B; \sigma) \rightarrow (C; \rho)$  are two functions then

- (i)  $g \circ f$  is r g-continuous, if  $f$  is continuous and  $g$  is r g-continuous.
- (ii)  $g \circ f$  is r g-irresolute, if  $f$  is r g-irresolute and  $g$  is r g-irresolute.
- (iii)  $g \circ f$  is r g-continuous, if  $f$  is r g-continuous and  $g$  is r g-irresolute.

Proof. (i) Consider  $f$  is r g-continuous and  $g$  is continuous respectively. Let  $V$  be closed in  $(Z; \rho)$ , then by definition of continuity  $g^{-1}(V)$  is closed in  $(B; \sigma)$  and r g-continuity of  $f$  implies  $f^{-1}(g^{-1}(V))$  is r g-closed in  $(A; \tau)$ . That is  $(g \circ f)^{-1}(V)$  is r g-closed in  $(A; \tau)$  where  $V$  is closed in  $(C; \rho)$ . Hence,  $g \circ f$  is r g-continuous.

(ii) Let  $f$  and  $g$  as defined above be r g-irresolute. Let  $V$  be r g-closed in  $(C; \rho)$ , then by definition of r g-irresolute function  $g^{-1}(V)$  is r g-closed in  $(B; \sigma)$ . As  $f$  is r g-irresolute  $f^{-1}(g^{-1}(V))$  is r g-closed in  $(A; \tau)$ . That is  $(g \circ f)^{-1}(V)$  is r g-irresolute in  $(A; \tau)$  where  $V$  is r g-irresolute in  $(C; \rho)$ . Therefore,  $g \circ f$  is r g-irresolute.

(iii) Let  $f$  and  $g$  as defined above be r g-irresolute and r g-continuous respectively. Let  $V$  be closed in  $(C; \rho)$ , then by definition of r g-continuity  $g^{-1}(V)$  is r g-closed in  $(B; \sigma)$ . As  $f$  is r g-irresolute so  $f^{-1}(g^{-1}(V))$  is r g-closed in  $(A; \tau)$ . That is  $(g \circ f)^{-1}(V)$  is r g-closed in  $(A; \tau)$  where  $V$  is closed in  $(C; \rho)$ . Therefore,  $g \circ f$  is r g-continuous.

4 Quasi r g-open functions

Definition 4. The map  $f : (A; \tau) \rightarrow (B; \sigma)$  known as r g-open map if the image

$(X)$  is  $r$ - $g$ -open in  $(B; \tau)$  for all open set  $X$  in  $(A; \tau)$ .

Definition 5. A function  $f : (A; \tau) \rightarrow (B; \tau)$  known as Quasi  $r$ - $g$ -open if the image of all  $r$ - $g$ -open set in  $A$  be open in  $B$ .

Example 4. Let  $A = \{l, m, n\}$ ,  $\tau = \{\emptyset, A\}$ ;  $f : A \rightarrow B$ ;  $f(l) = m$ ,  $f(m) = n$  and  $f(n) = n$ . We have the collection of  $r$ - $g$ -open set in  $(A; \tau)$  are  $\{l, m, n\}$ .

Now we see the image of each  $r$  g-open subset maps into open set of  $(B; \tau)$ .  
 Finally, by definition 5 is Quasi  $r$  g-open.

Theorem 5. A function  $f : (A; \tau) \rightarrow (B; \tau)$  known as Quasi  $r$  g-open if for

all subset  $U$  of  $A$ ,  $(r g \text{ int}(U)) \subseteq \text{int}(f(U))$ .

Proof. Let  $f$  be the Quasi  $r$  g-open function and  $U$  be a subset of  $A$ . Now, we have  $\text{int}(U) \subseteq U$  and  $r g \text{ int}(U)$  be a  $r$  g-open set. Thus we get that  $(r g \text{ int}(U)) \subseteq U$ . As  $(r g \text{ int}(U))$  is open  $(r g \text{ int}(U)) \subseteq \text{int}(U)$ . On the other hand, expect that  $U$  be a  $r$  g-open set in  $A$  then  $\text{int}(U) = (r g \text{ int}(U)) \subseteq \text{int}(U)$  but  $\text{int}(U) \subseteq U$ . Consequently,  $\text{int}(U) = \text{int}(r g \text{ int}(U))$  and hence  $f$  is Quasi  $r$  g-open.

Theorem 6. If a function  $f : (A; \tau) \rightarrow (B; \tau)$  be Quasi  $r$  g-open then  $r g \text{ int}(f(G)) \subseteq \text{int}(G)$  for all subset  $G$  of  $B$ .

Proof. Consider  $G$  to be any arbitrary subset of  $B$ . At that point,  $r g \text{ int}(f(G))$  is a  $r$  g-open set in  $A$  and  $B$  be a Quasi  $r$  g-open, then,  $(r g \text{ int}(f(G))) \subseteq \text{int}(f(G)) \subseteq \text{int}(G)$ . Thus,  $r g \text{ int}(f(G)) \subseteq \text{int}(G)$ . Review that a subset  $S$  is known as a  $r$  g-neighbourhood of a point  $a$  of  $A$ , if  $\exists$  a  $r$  g-open set  $U$  s.t.  $a \in U \subseteq S$ .

Definition 6. A map  $f : (A; \tau) \rightarrow (B; \tau)$  is known as a  $r$  g-closed map if the image  $f(A)$  is  $r$  g-closed in  $(B; \tau)$  for each closed set  $A$  in  $(A; \tau)$ .

Definition 7. A function  $f : A \rightarrow B$  is known as Quasi  $r$  g-closed if the image of each  $r$  g-closed set in  $A$  is closed in  $B$ . i.e. each Quasi  $r$  g-closed function is closed as well as  $r$  g-closed.

Definition 8. A function  $f : (A; \tau) \rightarrow (B; \tau)$  is known as  $r$  g-closed if  $r$  g-closed set  $F$  of  $A$ ,  $f(F)$  be  $r$  g-closed in  $B$ .

Example 5. Let  $A = B = \{l, m, n\}$ ;  $\tau = \{ \emptyset, A \}$ ;  $\tau = \{ \emptyset, B \}$ . Define a function  $f : (A; \tau) \rightarrow (B; \tau)$  by  $f(l) = m$ ,  $f(m) = n$  and  $f(n) = l$ .

Here, we have the collections of  $r$  g-closed sets in  $(A; \tau)$  and  $(B; \tau)$  are  $\{ \emptyset, A \}$ ;  $\tau = \{ \emptyset, B \}$  respectively. Now, for each  $r$  g-closed set in  $(A; \tau)$  function  $f$  maps into  $r$  g-closed set in  $(B; \tau)$ . Therefore,  $f$  is  $r$  g-closed.

Theorem 7. If  $f : (A; \tau) \rightarrow (B; \tau)$  and  $g : (B; \tau) \rightarrow (C; \tau)$  are two functions. Then

- (i)  $\alpha$  is closed if  $\alpha$  is  $r$   $g$ -closed and  $\alpha$  is Quasi  $r$   $g$ -closed.
- (ii)  $\alpha$  is  $r$   $\wedge$   $g$ -closed if  $\alpha$  be Quasi  $r$   $\wedge$   $g$ -closed and  $\alpha$  is  $r$   $\wedge$   $g$ -closed.
- (iii)  $\alpha$  is Quasi  $r$   $\wedge$   $g$ -closed if  $\alpha$  is  $r$   $\wedge$   $g$ -closed and  $\alpha$  is Quasi  $r$   $\wedge$   $g$ -closed.

Proof. (i) Here  $\alpha$  be  $r$   $g$ -closed and  $\alpha$  be Quasi  $r$   $g$ -closed. To prove  $\alpha$  be  $r$   $\wedge$   $g$ -closed. Let  $F$  be arbitrary closed in  $(A; \tau)$ . If,  $\alpha(F)$  be  $r$   $g$ -closed so  $(F)$  be  $r$   $g$ -closed in  $(B; \tau)$ . Also  $\alpha(F)$  be Quasi  $r$   $g$ -closed so  $(F)$  is closed in  $(C; \tau)$ . i.e.

On  $r$   $g$ -continuous functions in topological spaces 5

$\phi(F)$  is closed in  $(C; \tau)$  where  $F$  be closed set in  $(A; \tau)$ . Thus,  $\phi$  is closed.

(ii) Here be Quasi  $r$   $g$ -closed and be  $r$   $g$ -closed. To prove  $\phi$  be  $r$   $g$ -

closed. Let  $F$  be arbitrary  $r$   $g$ -closed in  $(A; \tau)$ . If,  $\phi$  be Quasi  $r$   $g$ -closed so  $\phi(F)$

be closed in  $(B; \tau)$  also,  $\phi$  is  $r$   $g$ -closed so  $(\phi(F))$  is  $r$   $g$ -closed in  $(C; \tau)$ . i.e.

$\phi(F)$  is  $r$   $g$ -closed in  $(C; \tau)$  where  $F$  be  $r$   $g$ -closed set in  $(A; \tau)$ . Thus  $\phi$  is

$r$   $g$ -closed.

(iii) Here  $\phi$  be  $r$   $g$ -closed and  $\phi$  be Quasi  $r$   $g$ -closed. To prove  $\phi$  is Quasi

$r$   $g$ -closed. Let  $F$  be arbitrary  $r$   $g$ -closed in  $(A; \tau)$ . Since  $\phi$  is  $r$   $g$ -closed so

$\phi(F)$  is  $r$   $g$ -closed in  $(B; \tau)$  also  $\phi$  is Quasi  $r$   $g$ -closed so  $(\phi(F))$  is closed in

$(C; \tau)$ . i.e.  $\phi(F)$  is closed in  $(C; \tau)$  where  $F$  be  $r$   $g$ -closed set in  $(A; \tau)$ . Thus,

$\phi$  is Quasi  $r$   $g$ -closed.

Theorem 8. If  $\phi : (A; \tau) \rightarrow (B; \tau)$  and  $\psi : (B; \tau) \rightarrow (C; \tau)$  are two functions such that  $\psi \circ \phi : (A; \tau) \rightarrow (C; \tau)$  be Quasi  $r$   $g$ -closed. Then

(i) If  $\phi$  be  $r$   $g$ -irresolute surjective, then  $\psi$  be Quasi  $r$   $g$ -closed.

(ii) If  $\psi$  be  $r$   $g$ -continuous injective, then  $\phi$  be  $r$   $g$ -closed.

Proof. (i) Here  $\phi : (A; \tau) \rightarrow (B; \tau)$  and  $\psi \circ \phi : (A; \tau) \rightarrow (C; \tau)$  are  $r$   $g$ -irresolute surjective and Quasi  $r$   $g$ -closed respectively. To show  $\psi$  is Quasi  $r$   $g$ -closed. Let  $F$  be  $r$   $g$ -closed in  $(B; \tau)$  as  $\phi$  is  $r$   $g$ -irresolute, so  $\phi^{-1}(F)$  is  $r$   $g$ -closed in  $(A; \tau)$ . As  $\psi \circ \phi$  is Quasi  $r$   $g$ -closed and  $\phi$  is surjective. Thus,  $\psi(\phi^{-1}(F)) = \psi(F)$  and closed in  $(C; \tau)$ , that is,  $\psi(F)$  be closed in  $(C; \tau)$  where  $F$  is  $r$   $g$ -closed in  $(A; \tau)$ .

Therefore,  $\psi$  is Quasi  $r$   $g$ -closed.

(ii) Here  $\psi : (B; \tau) \rightarrow (C; \tau)$  and  $\phi : (A; \tau) \rightarrow (B; \tau)$  are  $r$   $g$ -continuous injective and Quasi  $r$   $g$ -closed respectively. To show  $\phi$  is  $r$   $g$ -closed. Let  $F$  be  $r$   $g$ -closed in  $(A; \tau)$  as  $\phi$  is Quasi  $r$   $g$ -closed, so  $\phi(F)$  be closed in  $(B; \tau)$ .

Again  $\psi$  be  $r$   $g$ -continuous and injective function. Thus,  $\psi(\phi(F)) = \psi(F)$ , which is  $r$   $g$ -closed in  $(C; \tau)$ , that is,  $\psi(F)$  is  $r$   $g$ -closed in  $(C; \tau)$ , where  $F$  is  $r$   $g$ -closed in  $(A; \tau)$ . Thus  $\phi$  is  $r$   $g$ -closed.

5 On Regular generalized  $(r, g)$ -Compactness in Topological Space

In this section we extend the concept of open cover and compactness in the form

of  $r$   $g$ -closed sets to introduce  $r$   $g$ -open cover and  $r$   $g$ -compactness and discuss their properties and characterization.

Definition 9. The collection  $\{G_j : j \in J\}$  of  $r$   $g$ -open sets in a topological space  $A$  is known as  $r$   $g$ -open cover of a subset  $S$  if  $S \subseteq \bigcup_{j \in J} G_j$  holds.

Definition 10. The topological space  $(A, \tau)$  is known as  $r$   $g$ -compact if  $r$   $g$ -open cover of  $A$  has a finite sub cover.

Definition 11. A subset  $S$  of a topological space  $(A, \tau)$  is known as  $r$   $g$ -Compact relative to  $A$  if collection  $\{G_j : j \in J\}$  of  $r$   $g$ -open subsets of  $A$  such that  $S \subseteq \bigcup_{j \in J} G_j$  has a finite subset  $\{G_{j_1}, G_{j_2}, \dots, G_{j_n}\}$  of  $\{G_j : j \in J\}$  such that  $S \subseteq \bigcup_{i=1}^n G_{j_i}$ .

Definition 12. A subset  $S$  of a topological space  $A$  is known as  $r$ -g-Compact if  $S$  is  $r$ -g-Compact as a subspace of  $A$ .

Theorem 9. Let  $f : (A; \tau) \rightarrow (B; \sigma)$  is a surjective and  $r$ -g-continuous map. If  $A$  is  $r$ -g-compact, then  $B$  is compact.

Proof. Here, we have  $f : (A; \tau) \rightarrow (B; \sigma)$  a surjective and  $r$ -g-continuous map and  $A$  be  $r$ -g-compact. To prove  $B$  be compact. Let  $\{G_j : j \in \mathbb{N}\}$  is an open  $r$ -g-open cover of space  $A$ . As,  $A$  is  $r$ -g-compact, it has a finite sub cover, say  $\{G_1, G_2, G_3, \dots, G_n\}$ . Surjectiveness of  $f$  implies  $f(G_1), f(G_2), f(G_3), \dots, f(G_n)$  is an open cover of  $B$ . Therefore,  $B$  be compact.

Theorem 10. For a map  $f : (A; \tau) \rightarrow (B; \sigma)$  is  $r$ -g-irresolute and a subset  $S$  of  $A$  is  $r$ -g-compact relative to  $B$ , then the image  $f(S)$  is  $r$ -g-compact relative to  $B$ .

Proof. Here, we have  $f : (A; \tau) \rightarrow (B; \sigma)$  is  $r$ -g-irresolute also  $S$  subset of  $A$  is  $r$ -g-compact relative to  $A$ . To prove  $f(S)$  is  $r$ -g-compact relative to  $B$ . Let  $\{G_j : j \in \mathbb{N}\}$  be a collection of  $r$ -g-open sets in  $B$  such that  $f(S) \subseteq \bigcup_{j \in \mathbb{N}} G_j$ . Then for each  $j$ . Since  $S$  is  $r$ -g-compact relative to  $A$ , there exist a finite subcollection  $\{G_1, G_2, G_3, \dots, G_n\}$  such that  $S \subseteq \bigcup_{i=1}^n f^{-1}(G_i)$  i.e.  $f(S) \subseteq \bigcup_{j \in \mathbb{N}} G_j$ . Hence,  $f(S)$  is  $r$ -g-compact relative to  $B$ .

Theorem 11. A  $r$ -g-closed subset of a  $r$ -g-compact space  $A$  is  $r$ -g-compact relative to  $A$ .

Proof. Consider  $M$  is a  $r$ -g-closed subset of a  $r$ -g-compact space  $A$ . Therefore,  $A \setminus M$  be  $r$ -g-open in  $A$ . Now to prove  $M$  is  $r$ -g-compact relative to  $A$ . Let  $\{U_\alpha : \alpha \in I\}$  be a  $r$ -g-open cover for  $M$ . Then  $\{U_\alpha : \alpha \in I\} \cup \{A \setminus M\}$  be a  $r$ -g-open cover for  $A$ . As,  $A$  be  $r$ -g-compact, by definition 12,  $X$  has a finite subcover, say  $\{U_1, U_2, U_3, \dots, U_n\} \cup \{A \setminus M\}$ . If  $A \setminus M$  does not belong, then  $\{U_1, U_2, U_3, \dots, U_n\}$  is a subcover of  $M$ . Thus by definition 12  $M$  is  $r$ -g-compact relative to  $A$ .

6  $r$ -g-Closure

Definition 13. For a subset  $X$  of  $(A; \tau)$ , we define the  $r$ - $g$ -closure of  $X$  as follows:

$$r\text{-}g\text{-}cl(X) = \{F : F \text{ is } r\text{-}g\text{-}closed \text{ in } A; X \subseteq F\}$$

Theorem 12. Let  $X$  be a subset of  $(A; \tau)$  and  $a \in A$ . Then  $a \in r\text{-}g\text{-}cl(X)$  if and only if  $a \in \bigcap \{V : V \text{ is } r\text{-}g\text{-}open \text{ and } X \subseteq V\}$ .

$$r\text{-}g\text{-}cl(X) = \bigcap \{V : V \text{ is } r\text{-}g\text{-}open \text{ and } X \subseteq V\}$$

Proof. Let  $V$  be an  $r$ - $g$ -open set containing  $a$ .

$X \subseteq V$ ,  $r\text{-}g\text{-}cl(X) \subseteq V$  and then  $a \in r\text{-}g\text{-}cl(X)$ .

Proof. Let there be an  $r$ - $g$ -open set  $V$  containing  $a$  so that  $V \not\subseteq r\text{-}g\text{-}cl(X)$ .

Since  $V$  is  $r$ - $g$ -open,  $V \cap r\text{-}g\text{-}cl(X) = \emptyset$ .

This is a contradiction.

On r g-continuous functions in topological spaces

7

Conversely, let a 2= r g cl(X); then 9 a r g-closed set F containing X s.t a 2= F . Since a 2 A n F and A n F is r g-open, (A n F) X = , which is a

contradiction.

Theorem 13. Let X and Y be subsets of (A; ). Then

- (a) r g cl( ) = and r g cl(A) = A
- (b) If X Y , then r g cl(X) r g cl(Y)
- (c) r g cl(X) = r g cl(r g cl(X))
- (e) r g cl(X S Y) = r g cl(X) S r g cl(Y)
- (d) r g cl(X Y) = r g cl(X) r g cl(Y)

A, F g = . Hence, proved.  
Proof. (a) By using the de nition 13 r g cl( ) = F : F is a r g-closed in

r g-closed in A, Y F g. As X Y implies X F where F is a r g-closed in A, Y F g. As X Y implies X F where F is a r g-closed in A, Y F g.

(b) Here X Y and by using de nition 13 we have r g cl(Y) = fF : F is a r g-closed in A. i.e. r g cl(X) r g cl(Y). Hence, proved.

in A, X F g, So, r g cl(r g cl(X)) = r g cl(T fF : F is a r g-closed in A, X F g). Hence, proved.

(c) By using the de nition 13, we have r g cl(X) = fF : F is a r g-closed in A, X F g). Hence, proved.

(d) r g cl(X Y) = fF : F is a r g-closed in A, X Y F g ffF : F is a r g-closed in A, X Y F g). Hence, proved.
