## Abstract

In this paper Lexicographic Approach is used to solve a three Dimensional Travelling salesman problem. Three dimensional travelling salesman problem have different cost between two cities at different time. So a Salesman is to make a tour in such a way that it travels a station once and no station is left unvisited. The tour must be chosen in the manner that Cost must be minimum for the optimum tour, taking consideration of different time. The Travelling salesman problem is different as for n-city problem , n-zones of time are given and the cost between every two pair of cities is different for different time zones. And the tour is so chosen that at one time zone salesman visits only one pair of cities .The Lexicographic algorithm is developed in this paper to solve this type of problem.The Lexicographic algorithm is highly effective in respect of time consumption and calculating steps and size of complexity .The lexicographic algorithm presented in this paper is simpler than the lexicographic algorithm available in literature .A numerical example is also given after the algorithm.

**Keywords :**Lexicographic approach, Three dimensional Travelling salesman problem.

## 1.INTRODUCTION

Travelling salesman problem is a classical problem in combinatorial optimization. Since 1950's it has been studied intensively. As a result of it, a large number of techniques were developed to solve the problem. The objective of the problem is to find the shortest route of salesman starting from a given city, visiting all other cities only once and finally come to the same city where he started. There are different approaches for solving travelling salesman problems. Linear programming method, heuristic methods like cutting plan algorithms and branch and bound method, Markov chain, simulated annealing and tabu search methods. Few more algorithms like particle swarm optimization, neural networks, evolutionary computations, ant system, artificial bee colony, etc., are also there.

There are certain approaches for the exact solution of TSP and they are

1. Integer Programming.
2. Dynamic Programming
3. Branch and bound algorithm.
4. Lexicographic Search Method.

Vijyalaxmi G.[14] gave Lexicographic approach to travelling salesman problem, Sobhan Babu,K et al[11] gave an algorithm for travelling salesman problem, Venkatadri Naidu et al [13] gave optimization of service operations sequencing a four wheeler at service centre. Liu, G.et al[7] gave, a novel adaptive search strategy of intensification and diversification in tabu search .Our interest is in Lexicographic search. Section 2 of this paper contains definition of Lexicographic search. Section 3 has Mathematical formulation of the Travelling salesman problem ,Definitions of the terms used in the Algorithm developed in the paper and The Lexicographic Algorithm itself. Section 4 is Numerical Illustration and Section 5 is conclusion.

## 2. LEXICOGRAPHIC METHOD :

Let a,b,c,d are the name of the stations on which the salesman is to visit. Lexicographic method works as following.

It is just like Dictionary method. when a salesman starts from station 'a' it can go the stations 'b', 'c', 'd' so the route becomes 'ab', 'ac', 'ad'. Let 'ab' is the selected route then next route may be 'abc' or 'abd'. Now let 'abc' is the route then 'abcd' is the only way. Rest can be understood by the above figure.

## 3.1 MATHEMATICAL FORMULATION:

A n-city three dimensional travelling salesman problem can be mathematically stated as

$$\text{Minimize } Z = \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n C(i, j, k) X(i, j, k)$$

Subject to

$$\sum_{i=1}^n \sum_{j=1}^n X(i, j, k) = 1 \quad k = 1, 2, \dots, \dots, \dots, n$$

$$\sum_{j=1}^n \sum_{k=1}^n X(i, j, k) = 1 \quad i = 1, 2, \dots, \dots, \dots, n$$

$$\sum_{i=1}^n \sum_{k=1}^n X(i, j, k) = 1 \quad j = 1, 2, \dots, \dots, \dots, n$$

$X(i, j, k) = 1$  or  $0$ , represents the salesmen's visit, when salesman visits city  $j$  from city  $i$  at time  $k$  or otherwise.

X will be a feasible solution if it gives a tour for the salesman who visits the n cities with the condition that at a point of time in his tour he will not visit more than one pair of cities.

**3.2 Concepts and Definitions**

**3.2 (a) Definition of a Pattern**

An indicator three-dimensionally array which is associated with a tour is called a 'pattern' A pattern is said to be feasible if X is a feasible solution. The pattern represented in the table -4.2 is a feasible pattern.

It can be noticed that at a given time k the matrix X (i,j,k) (i,j, = 1,2,3,4) has for any one element the value 1 and for all the elements are zeros. This indicates that at time k if x (i,j,k)=1 then he visits city j from city i.

Now V (X) the value of the pattern x is defined as

$$V (X) = \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n C (i, j, k) X (i, j, k)$$

The value V (x) gives the total cost of the tour for the solution represented by X. Thus the value of the feasible pattern gives the total cost represented by it. In the algorithm, which is developed in the sequel, a search is made for a feasible pattern with the least value. Each pattern of the solution x is represents the set of ordered triples [(i,j,k) for which x (i,j,k) = 1 with the understanding that the other x (i,j,k)'s are zeros. The ordered triple set [(2,4,1), (1,3,2), (4,1,3), (3,2,4)] represents the pattern given in the Table -4.2, which is a feasible solution.

There are n<sup>3</sup> ordered triple in the three dimension array x, for convenience these are arranged in ascending order of their corresponding costs and are indexed from 1 to n<sup>3</sup>. Let SN = [1.2...n<sup>3</sup>] be the set of n<sup>3</sup> indices. Let D be the corresponding array of distances. If  $\alpha, \beta \in SN$  and  $\alpha < \beta$  then  $D (\alpha) \leq D (\beta)$ . Also let the arrays R, C and T be the array of row, column and time indices of the ordered triples represented by SN and DC be the array of cumulative sums of the elements of D.

The arrays SN, D, DC, R, C, T for the numerical example are given in the Table 4.3. If  $P \in SN$  then [R(P), C (P), T (P),] is the ordered triple and  $D (a) = [R(a),C(a),T(a)]$  is the value of the ordered triple and  $DC (a) = \sum_{i=1}^a D (i)$

**3.2 (b) Definition of an alphabet - Table and a word**

Let  $L_k = \{a_1, a_2, \dots a_k, \}$   $a_j \in SN$  be an ordered sequence of k indices from SN. The pattern represented by the ordered triples whose indices are given by  $L_k$  is independent of the order of  $a_i$  in the sequence. Hence for uniqueness the indices are arranged in the increasing order such that  $a_j \leq a_{j+1}$ ,  $i = 1, 2, \dots n-1$ . The set SN is defined as the "Alphabet - Table" with alphabetic order as (1,2,3 ... n<sup>3</sup>) and the ordered sequence  $L_k$  is defined as a "word" of length k. A word  $L_k$  is called a "sensible word", if  $a_i < a_{j+1}$  for  $i = 1, 2, \dots k-1$  and if this condition is not met it is called a "insensible word".

A word  $L_k$  is said to be feasible if the corresponding pattern x is feasible and same is with the case of infeasible and partial feasible Therefore a partial feasible word is said to be feasible if  $k = n$ . A partial word  $L_k$  is said to be feasible if the block of words represented by  $L_k$  has at least one feasible word or equivalently the partial pattern represented by  $L_k$  should not have any inconsistency.

Any of the letters in SN can occupy the first place in the partial word  $L_k$ . Consider  $L_{k-1} = (a_1, a_2, \dots a_{k-1})$ . The alphabet for the k<sup>th</sup> position is  $SN_{a_{k-1}} = (a_{k-1}+1, a_{k-1}+2, \dots N^3)$

$SN_p$  is defined as  $SN_p = (p +1, p+2, \dots n^3)$ . Thus for example consider a word with two letters as  $(a_1, a_2) = (1,3)$ . Then  $SN_{a_2} = SN_3 = (4, 5, 6 \dots 64)$  is the alphabet for the third position. We concentrate on the set of words of length almost n (for the numerical example it is 4). A leader  $L_k$  ( $k < n$ ) is said to be feasible, if the block of words defined by it contains at least one feasible word or equivalently there should not be inconsistency in the partial pattern defined by the partial word. The value of the  $L_k$ ,  $V(L_k)$  is defined recursively as

$V (L_k) = V (L_{k-1}) + D (a_k)$  with  $V (L_0) = 0$  obviously this  $V (L_k)$  and  $V (X)$  the values of the pattern X represented by  $L_k$  will be same. For example consider  $L_3 = (1,2,5)$ . Then  $V (L_3)$  will be  $V (L_3) = 0+0+0= 0$ .

**3.2 (c) Lower bound of a partial word LB (L<sub>k</sub>)**

A lower bound LB (L<sub>k</sub>) for the values of the block of words represented by  $L_k$  can be defined as follows:

$$\begin{aligned} LB (L_k) &= V (L_k) + \sum_{j=1}^{n-k} D (a_k + j) \\ &= V (L_k) + DC (a_k + n-k) - DC (a_k) \end{aligned}$$

Consider the partial word  $L_3$

$$\begin{aligned} V(L_3) &= 0+0+0=0 \\ LB (L_3) &= V (L_3) + DC (a_3 + 4-3) - DC (a_3) \\ &= 0 + DC (8+4-3) - DC (8) \\ &= DC (9) - DC (8) \\ &= 1 - 0 = 1 \end{aligned}$$

**3.2 (d) Algorithm for - feasibility criterion of a partial word**

A recursive algorithm is developed for checking the feasibility of a partial word  $L_{k+1} = (a_1, a_2, \dots a_k, a_{k+1})$  given that  $L_k$  is a feasible partial word. We will introduce some more notations which will be useful in the sequence

- RI Be an array where RI (i) = 1,  $i \in N$  represents that the salesman is visiting some city from city i, otherwise zero. (It represents that salesman is visiting or not visiting from city i, for that RI (i)=1 or 0)
- CI be an array where CI (i) = 1,  $i \in N$  represents that the salesman is coming to city i from some city; otherwise CI (i) = 0.
- TI be an array where TI (i) = 1,  $i \in N$  represents that the salesman at time i travels one pair of cities.
- SW be an array where SW (i) is the city that the salesman is visiting from city i and SW (i) = 0 indicates that the salesman is not visiting any city from city i.
- L Be an array where L (i) is the letter in the i<sup>th</sup> position of a word. Then for a given partial word  $L_k (a_1, a_2, \dots a_k)$  the values of the arrays RI, CI, TI, SW, L are as follows.
  - for other elements of j.  $RI [R (a_i)] = 1, i = 1, 2, \dots k$  and  $RI (j) = 0$
  - for other elements of j.  $CI [C (a_i)] = 1, i = 1, 2, \dots k$  and  $CI (j) = 0$  for
  - other elements of i.  $TI (T (a_i)) = 1, i = 1, 2, \dots k$  and  $TI (j) = 0$  for other
  - elements of i.  $SW [R(a_i)] = C (a_i) i = 1, 2, \dots k$  and  $SW (j)=0$  for other

elements of  $j$ .  $L(i) = a_i, i = 1, 2, \dots, k, L(i) = 0 \quad i > k$

For example consider a sensible partial word  $L_3 = (1,6,8)$  which is feasible. The arrays RI, CI, TI, SW and L takes the values represented in the Table -4.4

The recursive algorithm for checking the feasibility of a partial word  $L_{p-1}$  is given as follows. In this algorithm  $L_p$  is a feasible word. We test the following tips for introducing  $a_{p+1}$  in the  $L_p$

In the algorithm, first we equate  $XI = 0$ . At the end if  $XI = 1$  then the partial word  $L_{p+1}$  is feasible. Otherwise it is infeasible.

**THE ALGORITHM**

```

STEP 1      XI = 0
            GOTO 2
STEP 2      IS [RI {R (ap + 1)}] = 1      IF YES GOTO 8
            IF NO GOTO 3
STEP 3      IS [CI {C (ap + 1)}] = 1      IF YES GOTO 8
            IF NO GOTO 4
STEP 4      IS [TI {T (ap + 1)}] = 1      IF YES GOTO 8
            IF NO GOTO 5
STEP 5      IS [SW {C (ap + 1)}] = 0      IF YES XI =1 GOTO 8
            IF NO
            K = SW {C (ap+1)}
            GOTO 6
STEP 6      IS {K = R (ap + 1)}          IF YES GOTO 7
            IF NO, Assume C (ap+1) = K
            GOTO 5
STEP 7      IS (I = N)                    IF YES XI =1 GOTO 8
            IF NO GOTO 8
STEP 8      STOP
    
```

This recursive algorithm can also be used as a subroutine in the Lexi - search algorithm. We start the algorithm with a very large value say 999 as a trial value of VT. If the value of a feasible word is known we can as well start with that value as VT. During the search the value of VT is improved. At the end of the search the current value of VT gives the optimal feasible word. We start with the partial word  $L_1(a_1) = (1)$ . A partial word  $L_p$  is constructed as  $L_p = L_{p-1} * (a_p)$ , where \* indicates chain form or concatenation. We will calculate the values of V ( $L_p$ ) and LB ( $L_p$ ) simultaneously. Then two cases arise one for branching and other for continuing the search.

- 1-  $LB(L_p) < VT$ . Then we check whether  $L_p$  is feasible or not. If it is feasible we proceed to consider a partial word of order (P+1), which represents a sub block of the block of words represented by  $L_p$ . If  $L_p$  is not feasible then consider the next partial word of order p by taking another letter which succeeds  $a_p$  in the  $P^{th}$  position. If all the words of order P are exhausted then we consider the next partial word of order (P-1).
- 2-  $LB(L_p) \geq VT$ . In this case we reject the partial word, meaning that the block of words with  $L_p$  as leader is rejected for not having an optimal word and we also reject all partial words of order P that succeeds  $L_p$ .

Now we are in a position to develop a lexi-search algorithm to find an optimal feasible word.

**3.3 Lexi - Search Algorithm For Optimal Feasible Word**

The following algorithm gives an optimal feasible word.

```

STEP 1:      (Initialization) The arrays SN, D, DC, R, C, T and N are made available
            RI, CI, TI, SW, L, V, LB are initialized to zero.
            The values I = 1, J = 0, VT = 999, NZ = N*N*N-N, MAX = NZ-I. (I stands for ith letter of the word)
STEP 2 :      J = J+1
            MAX) IF YES GOTO 10
            IF NO GOTO 3
STEP 3 :      L (I) = J
            N - I
            V (I) = V (I-1) + D (J)
            LB (I) = V(I) + DC (JA) - DC (J)
            GOTO 4
STEP 4 :      IS (LB (I) ≥ VT)
            IF YES GOTO 11
            IF NO GOTO 5
STEP 5 :      CHECK THE FEASIBILITY OF L
            ALGORITHM) IF YES GOTO 2
            IF NO GOTO 6
STEP 6 :      IS (I = N)
            IF YES GOTO 9
            IF NO GOTO 7
STEP 7 :      L (I) = J
            = 1
            RI {R(J)}
            CI {C(J)} = 1
            TI {T(J)} = 1
            SW {R (J)} = C (J)
            GOTO 8
STEP 8 :      I = I+1
            MAX -1
            GOTO 2
STEP 9 :      L (I) = J
            full length word and is feasible VT = V (I),
            Record L (I), VT
            GOTO 11
    
```

```

STEP 10      :      IS (I=1)                IF YES GOTO 13
              IF NO GOTO 1
STEP 11      :      I = I-1
              MAX = MAX +1                    GOTO 12
STEP 12      :      J = L (I)
              RI {R (J)} =0                    CI {C(J)} =0
              SW {R(J)} =0                    TI {T (J)} =0
              GOTO 2
STEP 13      :      STOP
              END
    
```

The current value of VT at the end of the search is the value of the Optimal feasible word. At the end if VT=999 it indicates that there is no feasible solution.

**4. NUMERICAL ILLUSTRATION :**

The concepts and the algorithm development will be illustrated by a numerical example for which n = 4 let N = [1,2,3,4] the cost array C (i, j, k) is given in the table-4.1.

**Table -4.1 Cost Matrix.**

$$C(i, j, 1) = \begin{pmatrix} 999 & 0 & 3 & 28 \\ 16 & 999 & 41 & 0 \\ 40 & 0 & 999 & 5 \\ 27 & 0 & 21 & 999 \end{pmatrix}$$

$$C(i, j, 3) = \begin{pmatrix} 999 & 26 & 24 & 34 \\ 15 & 999 & 29 & 20 \\ 37 & 2 & 999 & 0 \\ 32 & 0 & 31 & 999 \end{pmatrix}$$

$$C(i, j, 2) = \begin{pmatrix} 999 & 12 & 20 & 29 \\ 44 & 999 & 14 & 46 \\ 0 & 27 & 999 & 42 \\ 8 & 6 & 13 & 999 \end{pmatrix}$$

$$C(i, j, 4) = \begin{pmatrix} 999 & 30 & 36 & 42 \\ 8 & 999 & 0 & 25 \\ 17 & 7 & 999 & 50 \\ 19 & 5 & 38 & 999 \end{pmatrix}$$

In the numerical example given in Table -4.1, C (i,j,k) for i = j, i, j, k = 1,2,3,4 are taken to be very high number 999, because they are Irrelevant for finding tours of the salesman.

A 'tour' is a feasible trip- schedule for the salesman. Trip Schedule of the salesman can be represented by an appropriate (n × n × n) indicator array. X = {x (i, j, k)} | x (i, j, k) = 0 or 1} in which x (i, j, k) = 1

indicates that the salesman visits city j from city i at time (facility) k and if there is not such trip it is indicated by x (i, j, k) = 0. The indicator X given in Table -4.2 where the 4x4x4 of X is presented as four matrices for different values of k I, e., k = 1,2,3,4 to the numerical example.

**Table -4.2 - Indicator Matrix**

$$X(i, j, 1) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i, j, 3) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i, j, 2) = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i, j, 4) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

The representation of the solution X to the problem is that the salesman visits city 4 from city 2 at time 1, visits city 3 from city 1 at time 2, visits city 1 from city 4 at time 3 and visits city 2 from city 3 at time 4. This solution is a feasible solution.

The tour corresponding to Table 3.2 can be presented as

$$2 \rightarrow 4 \rightarrow 1 \rightarrow 3 \rightarrow 2$$

$$k = 1, k = 3, k = 2, k = 4$$

**Table 4.5 Search - Table**

The working details of getting an optimal word, using the algorithm 3.3 for the illustrated numerical example is given in the following table. The columns (1), (2), (3) and (4) gives the letters in the first, second, third and fourth places respectively. The corresponding V(I) and LB(I) are also indicated. Last column gives whether Rejected (R) or Accepted (A).

The partial word in 25<sup>th</sup> row is  $L_3 = (1,5,25)$  which is partially feasible. For this partial word the arrays RI, CI, TI, SW and L are given as the following Table -4.6

**Table -4.6** The arrays RI, CI, TI, SW and L for feasible Partial Word  $L_3=(1, 5, 25)$

	1	2	3	4
<b>RI</b>	1	1	1	0
<b>CI</b>	1	1	0	1
<b>TI</b>	1	1	1	0
<b>SW</b>	1	4	1	0
<b>L</b>	1	5	25	0

At the end of the search the current value of VT is 8 and it is the value of the optimal feasible word. The optimal feasible word is  $L_4 = (1,6,8,15)$ , it is given in 66<sup>th</sup> row of the search table. The pattern represented by the above optimal feasible word is represented in the following Table 4.7.

Table 4.7 Optimal Feasible Solution

$$X(i,j,1) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i,j,2) = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i,j,3) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}$$

$$X(i,j,4) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

The Tour represented by the above pattern is [(1,2,1), (4,1,2), (3,4,3), (2,3,4)] where the salesman from city 1 goes to city 2 at time 1, from city 2 goes to city 3 at time 4, from city 3 goes to city 4 at time 3 and from city 4 goes to city 1 at time 2. It can be seen that all cities and all times are involved in the optimal solution for the tour. It also can be represented by

$$1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 1 \\ k=1 \quad k=4 \quad k=3 \quad k=2$$

## 5. CONCLUSION :

In the Lexicographic search the structure of search algorithm does not require huge dynamic memory, so for large problems this method appears to be relatively smaller than to branch and bound method. The lexicographic algorithm thus developed in this paper, surely gives optimal tour of the salesman. As compared to the exponential space for branch and bound algorithm the lexicographic search takes a linear space. The procedure developed by others requires more variable and more constraint, to solve time dependent traveling salesman problem. The procedure developed by author takes care of the simple combinatorial structure of traveling salesman problem. So have lesser calculations. A computer program may be developed according to algorithm and the algorithm may be extended for Assignment problem also.
