## Abstract

We study topology over a non-empty set and define topological terms like open set, closed set, neighborhood at a point, adherent point, accumulation point, isolated point, interior, exterior, boundary, derived set and closure of a set, dense set, connected and disconnected sets, separated sets in a topological space. Also illustrate a single example which defines all the topological terms.

## Keywords

Basis, Clopen, Intersection, Isolated Point, Sub-basis, Union, Perfect set.

## Introduction

A **topology**<sub>1</sub>  $\tau$  over a non-empty set  $X$  is defined as a class  $O$  of subsets of  $X$  satisfying the conditions

1.  $X$  and the empty set  $\phi$  are in  $O$ .
2. Intersection of any finite family of  $O$  is in  $O$ .
3. Union of any arbitrary family of  $O$  is in  $O$ .

Then the set  $X$  together with the topology  $\tau$  is called **topological space**<sub>2</sub> denoted by  $(X, \tau)$  or simply by  $X$ . The sets in the collection  $O$  are called **open sets**<sub>3</sub> of  $X$ . A subset  $A$  in of  $X$  is **closed**<sub>4</sub> if it's complement  $A^c$  is open in  $X$ . A subset of  $X$  may be both open and closed set called clopen set. The set  $X$  itself and empty set  $\phi$  are always **clopen**<sub>5</sub> sets in a topological space  $(X, \tau)$ .

A subclass  $\beta$  of class  $O$  is called a **basis**<sub>6</sub> of topology  $\tau$  if every open set of  $X$  is a union of sets of  $\beta$  and a subclass  $\gamma$  of class  $O$  is called **sub-basis**<sub>7</sub> of topology  $\tau$  if the finite intersections of  $\gamma$  forms a basis for the topology  $\tau$ .

A set  $N$  in topological space  $X$  is called **neighbourhood**<sub>8</sub> (simply written by nhd.) of a point  $x \in X$ , if there exists an open set  $O_x$  containing point  $x$  such that  $x \in O_x \subseteq N$ . Superset of a nhd. of  $x$  is also a nhd. of  $x$ .

**Theorem-1** A set  $A$  in a topological space  $(X, \tau)$  is open iff  $A$  is a nhd. Of each of it's points.

*Proof:*  $A$  is a set in a topological space  $(X, \tau)$ .

Necessity: let  $A$  is open in  $X$ , then for every point  $x$  of  $A$ ,  $x \in A \subseteq A$ , therefore  $A$  is nhd. of  $x$  but  $x$  is arbitrary so  $A$  is a nhd. of each of its points.

Sufficiency: let  $A$  is a nhd. of each of it's points then for every point  $x \in A$ ,  $\exists$  open set  $O_x$  containing point  $x$  such that  $x \in O_x \subseteq A$  which implies that  $A \subseteq \bigcup_{x \in A} O_x \subseteq A \Rightarrow A = \bigcup_{x \in A} O_x$  but condition (3) of topology,  $\bigcup_{x \in A} O_x$  is open in  $X$  hence  $A$  is open in  $X$ . Which proves the theorem.

For a set  $A$  in  $X$ , a point  $x \in X$  is called an **adherent point**<sub>9</sub> of set  $A$  if every nhd. of  $x$  contains at least one point of  $A$ .

The collection of all adherent points of set  $A$  is called **adherence or closure**<sub>10</sub> of set  $A$  denoted by  $\bar{A}$ . Closure of set  $A$

can also be defined as the intersection of all closed sets contains the set  $A$  i.e.  $\bar{A}$  is the smallest closed set contains the set  $A$ . If  $A$  contains at least a single element in every nhd. of  $x$  other than the point  $x$ , then  $x$  is called a **limit point or accumulation point**<sub>11</sub> of set  $A$ . The collection of all limit points of  $A$  is called **derived set**<sub>12</sub> of  $A$  and denoted by  $A'$ .

Thus for  $x \in X$  and every nhd.  $N_x$  of  $x$ ;  $x \in \bar{A}$  iff  $N_x \cap A \neq \phi$  and  $x \in A'$  iff  $\{N_x - x\} \cap A \neq \phi$ .

**Theorem-2** For any set  $A$  in a topological space  $(X, \tau)$ ,  $\bar{A} = A \cup A'$ .

*Proof:* From def. (9) It is obvious that  $A \subseteq \bar{A}$  and also  $x \in A' \Rightarrow x \in \bar{A}$ ,  $\therefore A' \subseteq \bar{A}$  and hence  $A \cup A' \subseteq \bar{A}$  ..... (1)

Aim to prove  $A \cup A'$  is closed, let  $p \in (A \cup A')^c \Rightarrow p \notin (A \cup A') \Rightarrow p \notin A$  and  $p \notin A' \Rightarrow p \notin A$  and  $\exists$  an open set  $P$  containing point  $p$  such that  $[P - \{p\}] \cap A = \phi \Rightarrow P \cap A = \phi \Rightarrow P \subseteq A^c \Rightarrow p \in P \subseteq (A \cup A')^c \Rightarrow (A \cup A')^c$  is a nhd. of point  $p$  but  $p$  is arbitrary therefore  $(A \cup A')^c$  is nhd. of each of its points hence  $(A \cup A')^c$ .

Now  $(A \cup A')^c$  is open implies that  $A \cup A'$  is closed thus from def. (4)  $\bar{A} \subseteq A \cup A'$  .....(2)

From result (1) and result (2) we get the desired  $\bar{A} = A \cup A'$ .

For a set  $A$  in  $X$ , a point  $x \in A$  is called an **interior point**<sub>13</sub> of set  $A$  if  $A$  is a nhd. of point  $x$  i.e. there exists an open set  $O_x$  containing point  $x$  such that  $x \in O_x \subseteq A$ . The collection of all interior points of set  $A$  is called **interior**<sub>14</sub> of set  $A$  and denoted by  $A^\circ$ . It is obvious that  $A^\circ$  is the union of all open sets contained in set  $A$  hence  $A^\circ$  is the largest open set contained in set  $A$ . A point  $x \in X$  is called **exterior point**<sub>15</sub> of set  $A$  if  $x$  is an interior point of  $A^c$  and its collection is called **exterior**<sub>16</sub> of set  $A$ , denoted by  $\text{ext.}A$ . Thus  $\text{ext.}A = (A^c)^\circ$ . A point  $x \in X$  is called **frontier point**<sub>17</sub> of  $A$  if  $x$  is neither an interior point nor an exterior point and its collection is called **frontier**<sub>18</sub> denoted by  $\text{front.}A$ . A point  $x \in A$  is called **boundary point**<sub>19</sub> of set  $A$  if  $x \in \text{front.}A$  whose collection is called **boundary**<sub>20</sub> of set  $A$ .

A subset  $A$  of  $X$  is said to be **dense**<sub>21</sub> in  $X$  if  $\bar{A} = X$  and called **nowhere dense**<sub>22</sub> if  $\text{int}(\bar{A}) = \phi$  i.e.  $(\bar{A})^c$  is dense in  $X$ . The set  $A$  is said to be **perfect**<sub>23</sub> if  $A' = A$  and a point  $x \in X$  is called **isolated point**<sub>24</sub> of set  $A$  if  $x \in \bar{A}$  but  $x \notin A'$  therefore a subset  $A$  of  $X$  is called perfect if  $A$  is closed and has no isolated point (by theorem-2).

Two sets  $A$  and  $B$  in topological space  $X$  are said to be **separated**<sub>25</sub> if  $A$  and  $B$  are disjoint and also the derived set of any one is disjoint with the other i.e.  $A$  and  $B$  satisfy i)  $A \cap B = \phi$ . ii)  $\bar{A} \cap B = \phi$ . iii)  $A \cap \bar{B} = \phi$ .

A subset  $A$  of  $X$  is said to be **disconnected**<sub>26</sub> if there exist two open sets  $G$  and  $H$  in  $X$  such that  $A \subseteq G \cup H$  and the sets  $A \cap G$  and  $A \cap H$  are disjoint, then  $G \cup H$  is called disconnection of set  $A$ . The set  $A$  is said to be **connected**<sub>27</sub> if it is not disconnected.

**Example-1** Let  $X = \{a, b, c, d\}$  and  $\tau$  is a class of subsets of  $X$  given as  $\tau = \{\phi, X, \{a\}, \{a, b\}, \{c, d\}, \{a, c, d\}\}$ . Show that  $\tau$  is a topology on  $X$  and then define all terms of topology by taking suitable subset of  $X$ .

*Solution:* In the given class  $\tau$  we observe that the all three conditions of def.(1) are satisfied hence  $\tau$  is a topology on set  $X$  and with this topology,  $(X, \tau)$  is a topological space.

- i) Open sets in  $X$  are  $\phi, X, \{a\}, \{a, b\}, \{c, d\}$  and  $\{a, c, d\}$ .
- ii) Closed sets in  $X$  are  $\phi^c, X^c, \{a\}^c, \{a, b\}^c, \{c, d\}^c$  and  $\{a, c, d\}^c$  i.e.  $X, \phi, \{b, c, d\}, \{c, d\}$  and  $\{b\}$ .
- iii) Let a set  $A = \{a, b, c\}$  in  $X$ , obviously  $a, b$  and  $c$  are adherent points. Now open sets containing  $d$  are  $X, \{c, d\}$  and  $\{a, c, d\}$ , none of them is disjoint from  $A$ , therefore  $d$  is also an adherent point of  $A$ . hence by def.(10)  $\bar{A} = \{a, b, c, d\} = X$  so by def.(21)  $A$  is dense in  $X$ .

- iv) Since  $a$  belongs to open set  $\{a\}$  and  $(\{a\}-\{a\}) \cap A = \phi$ , and  $c$  belongs to open set  $\{c,d\}$  and  $(\{c,d\}-\{c\}) \cap A = \phi$  therefore  $a$  and  $c$  are not accumulation points and  $b$  and  $d$  are accumulation points of  $A$  therefore  $A' = \{b,d\}$ . Since  $a, c \in \bar{A}$  but  $a, c \notin A'$  so  $a$  and  $c$  are isolated points by def.(24) and hence by def.(23)  $A$  is not a perfect set.
- v) By def.(13)  $A^o = \{a,b\}$ . Since  $A^c = \{d\}$  which has no interior points so  $\text{ext.}A = \phi$  and hence by def.(18)  $\text{front.}A = \{c,d\}$  and  $c \in A$ , so by def.(19)  $c$  is only the boundary point of  $A$ .
- vi) Let  $P$  and  $Q$  are two open sets given as  $P = \{a,b\}$  and  $Q = \{c,d\}$ . Now we found that  $\bar{P} = \{c,d\}$  and  $\bar{Q} = \{a,b\}$  then i)  $P \cap Q = \phi$ , ii)  $\bar{P} \cap Q = \phi$ , iii)  $P \cap \bar{Q} = \phi$ . so by def.(25) the sets  $P$  and  $Q$  are separable in  $X$  hence the set  $P \cup Q = X$  is disconnected by def.(26).
- vii)  $A \cap P = \{a,b\}$  and  $A \cap Q = \{c\}$  then  $(A \cap P) \cap (A \cap Q) = \phi$  and  $A \subset P \cup Q$ , hence by def.(26)  $A$  is disconnected and  $P \cup Q = X$  is disconnection of set  $A$ .

### Result

All topological terms can be defined by a single example which shows that all topological terms are related in which open sets make important and independent role to define others.
