**Abstract-** Online social networks have produced bunch of online social groups where individuals can collaborate and exchange their ideas. The real problems that conflicts with the user security and convenience are confidentiality break, groups without inception, confusion created from various groups' difficulty in managing groups. This can be overcome to an extent by an automated filtering method required to categorizing group members based on their responses. This paper proposes clustering of group posts on thematic, emotional, stylistic, sentimental and psycholinguistic methods and group members are categorized based on their responses to the posts belonging to different clustering methods. This categorization helps to stop irrelevant notifications to the users which are received from more than one groups, via recommending the posts which might interest the users. It also helps to identify the group members those violate group policies by posting negative posts. The post categorization increases the performance where there are large numbers of members in a social group by performing linguistic clustering. The contribution work is to implement location-aware personalized posts recommendation using user's behavioral patterns and their geographic location. Another, important work is to implement text-to-speech system converting English text into speech using speech synthesis technique. The system gives user rating to the users who share posts depending on the cluster they belong to. The system provides read later post functionality to the users. The system also provides the users with hash-tag recommendations. The system also provides user with posts based on long - term and short - term analysis. The system has been tested on Twitter API group data where a significant solution to an unaddressed problem associated with social networking groups is offered.

**Keywords-** *Sentiment Analysis , Emotion Analysis, Multi-level Clustering, Psycholinguistics, LDA, Text to speech ,Stylistics Clustering, NLP, Vector Computation.*

## 1. INTRODUCTION

The most popular social networking site Twitter has groups with over 100K members in it. Hence it is difficult for the admin to track the members violating group policies. Thus there is immense need to categorize posts because posting articles irrelevant to these groups can create unnecessary clutter that affects the comfort of the members within the group. Unnecessary advertisements and marketing matters targeting a different audience should be avoided from a group. There is no existing method to deal with this. A method to control the influx of irrelevant messages within a community is essential for the smooth functioning of a social networking group. The existing policies of popular social networking site Twitter enable the administrator of a group to delete and monitor posts made by the members of a community. To screen all the messages posted by the members of a heavily populated group is very difficult. The existing settings provide no option for automated notification for

group admin with regard to the members involved in posting articles that do not match the general interest of the group. Our proposed method aims at providing an automated notification to the group moderators regarding suspicious members who frequently post articles that appear to gather negative response from the members within the group. Also provide user with posts based upon his interests. This system also gives the user rating based on the clustering. This novel approach has been experimented to account for the hypothesis that, though members may be socially connected; there might be disparity in their likings, thoughts, sentimental orientation and thematic inclination.

### 1.1 Motivation

To provide an automated notification to the group moderators regarding suspicious members who frequently post articles that appear to gather negative response from the members within the group.

## 2. RELATED WORK

The paper [1] proposes a new content based method for personalized tweet recommendation, based on conceptual relations between users' topics of interest. The Concept Graph is used to relate topics of interest in order to provide interesting and efficient tweet recommendations. Advantages are: Provides a social media user with a new timeline that contains messages that strongly match ones interests and that are not necessarily posted by ones followings. This model is effective and efficient to recommend interesting tweets to users. Disadvantages are: The recommender still recommends some tweets that were not retweeted by the user.

The paper [2] proposes a TWIMER framework the use of language models as a basis for analyzing strategies and techniques for tweet advice based on person's interest profiles. TWIMER consists of several components, including tweet retrieval (query formation and relevance model), tweet relevance verification, and final relevance ranking. Advantages are: Automatic query expansion. Higher performance in the language model retrieval entities.

In [3] paper, collaborative topic Poisson factorization (CTPF) can be used to build recommender systems through gaining knowledge of from reader histories and content material to advocate personalized articles of hobby. CTPF models both reader behavior and article texts with Poisson distributions, connecting to the latent subjects that represent the texts with the latent choices that shows to the readers. Advantages are: CTPF performs well in the face of massive, sparse, and long-tailed data. CTPF offers a natural mechanism to resolve the "cold start" hassle. CTPF scales more easily and provides significantly better recommendations than CTR.

In [4] paper, represents the trouble of concurrently predicting consumer decisions and modeling customers' interests in social media with the aid of reading rich statistics collected from Twitter. Proposes Co-Factorization Machines (CoFM), which deal with two (multiple) aspects of the dataset where each aspect is a separate FM. This type of model can easily predict user choices even as modeling user interests via content material at the equal time. Advantages are: CoFM can easily predict user decisions while modeling user interests through content at the same time. Factorization Machines to text data with constraints can mimic state-of-the art topic models and yet benefit from the efficiency of a simpler form of modeling. Disadvantages are: The services are only interacting with the user's interest not on user's behaviors.

The paper [5] focuses on recommending useful tweets that users are really interested in personally to reduce the users' effort to find useful information. The topic level latent factors of tweets to capture users' common interests over tweet content, which helps us to solve the problem of information sparsity in users' retweet actions. This allows us to adjust the collaborative filtering technique to solve the recommendation problem. Advantages are: A collaborative ranking method is better than collaborative filtering for different optimization criterion. The proposed CTR method greatly improves the recommendation performance. The CTR method is generic; it is easy to incorporate more information by adding extra features. Disadvantages are: It only works on user's interests over time not on user's history and tags of the tweet.

In [6] paper, fill the distance among current assessment-summarization and evaluation selection strategies with the aid of selecting a small subset of reviews that together hold the statistical properties of the whole assessment corpus. The proposed three heuristic algorithms for selecting a characteristic review set, which evaluate via experiments on a wide range of datasets of real reviews from different domains. Advantages are: To accurately emulate the opinion distribution in the underlying corpus. Improvement by previous work. Disadvantages are: Positive and negative comment can't generalize to arbitrary domain.

In [7] paper, consider the review set selection problem where given a set of reviews for a specific item, and want to select a comprehensive subset of small size. Provides authentic review using TOPQLTY algorithm sorting technique problem is based on limited review set. Advantages are: Performance is statically significant. High quality of the review.

The paper [8] presents proposed methods to compute quality, diversity and coverage properties using multidimensional content and context data. The proposed metrics so as to evaluate the picture summaries based totally on their illustration of the bigger corpus and the capacity to meet user's information needs. Advantages are: The greedy algorithm for summarization performs better than the baselines. Summaries help in effective sharing and browsing of the personal photos. Disadvantages are: Computation is expensive.

In paper [9], there are two methods for incorporating social context in the quality prediction: either as features, or as regularization constraints, based on a set of hypotheses. The method proposes quite generalizable and applicable for quality (or attribute) estimation of other types of user-generated content. Advantages are: Improve the accuracy of review quality prediction. The resultant predictor is utilizable even when social context is unavailable. Disadvantages are: A portal may lack an explicit trust network.

In multi-document summarization [10], redundancy is a particularly important issue since textual units from different documents might convey the same information. A high quality (small and meaningful) summary should not only be informative about the remainder but also be compact (non-redundant). Advantages are: The best performance is achieved. Submodular summarization achieves better ROUGE-1 scores. Disadvantages are: The proposed system very expensive to solve.

### 3. OPEN ISSUES

A method to control the irrelevant messages within a community is very much essential for the smooth functioning of a social networking group. The existing policies of popular social networking site Twitter enable the administrator of a group to delete and monitor posts made by the members of a community. To screen all the messages posted by the members of a heavily populated group is very difficult. The existing settings provide no option for automated notification for group admin with regard to the members involved in posting articles that do not match the general interest of the group.

Disadvantages are:

1. Does not solve the clutter issues and group policy management hassles associated with social networking groups.
2. None of the methods deal with the issue of providing customized suggestions to posts in a community to reduce clutter associated with notifications generated by large groups.
3. Does not provide automated notification for group admin with regard to the members involved in posting articles.
4. Need to categorize the posts made by members in it based on acceptability and group behavior.

### 4. SYSTEM OVERVIEW

The proposed method puts forward a filtering mechanism that enables a member of a social network community to get notified about posts that can be interesting to them. The method groups the members into different clusters

based on their aspect-based characterization. The members belonging to the same clusters are those who exhibit resemblances with respect to sentimental, thematic, emotional, writing style and concept-related interests.

There are 5 types of clustering methods:

#### 1) Sentiment Clustering

The posts in a network group vary based on the sentimental status associated with the contents. The overall sentiment associated with a post can be positive, negative or neutral. The assessment of the sentiment is made at the keyword level. This enables to classify the posts based on the attitude towards the trends.

#### 2) Theme Clustering

The next type of clustering performed on the posts is the theme based clustering. Here the posts are grouped based on the thematic similarities. After consider concepts, entities and topics for determining the theme. Use the semantically rich common sense knowledge base ConceptNet for extracting contextual and conceptual information of a post.

#### 3) Emotional Clustering

Emotion based aspects can be investigated to gain insight into a person emotional attitude. The similarity in these aspects can be exploited to predict the liking and sharing probability of members within a community. Thus, the users within a community are grouped together based on the emotional aspects. The clustering based on emotion is performed by taking into account the score of the entire post with respect to the emotional categories namely anger, sadness, fear, disgust and joy.

#### 4) Stylistic Clustering

Stylistics refers to the writing-style followed in a document. Each person has a unique writing style of his or her own. The writing-style factor has been considered because the writing style followed determines the popularity of an article. There are phrases and usages peculiar to authors that can be of interest to the audience. The stylistic features such as words and character n-grams can capture the writing style effectively. These features are clustered by using K-means clustering.

#### 5) Psycholinguistic Clustering

The posts have been subjected to the analysis of psycholinguistic orientation of the posts. The psycholinguistic differences contribute to the nature of the posts and hence there will be difference in the audience based on the psycholinguistic perspective of members within a group. Psycholinguistic aspects throw light on various factors that vary based on a person personality, hobbies, passions, intellects, perception and context of references. Thus it reflects a person way of responding to a post.

The contribution of the proposed method can be summed up as follows:

1. The method proposes a two-level clustering mechanism that aims at categorizing the members of a group based on interest.
2. The method is extended to provide features for group policy management.
3. The contribution work is to implement location-aware personalized posts recommendation using both the users' personal interests and their geographical contexts.
4. Another, important work is to implement text-to-speech system converting English text into speech using speech synthesis technique.
5. The system provides the read later posts functionality to the users.
6. The system gives rating to the users who shares posts depending on clustering.
7. The experiments have been conducted on limited content available for processing which makes the experiment standout from the state-of-the-art techniques that rely on lengthy text for processing.
8. This system provides user hashtag recommendations.
9. The system provides user with long term and short term posts recommendations.
10. The method is scalable in huge data-set.

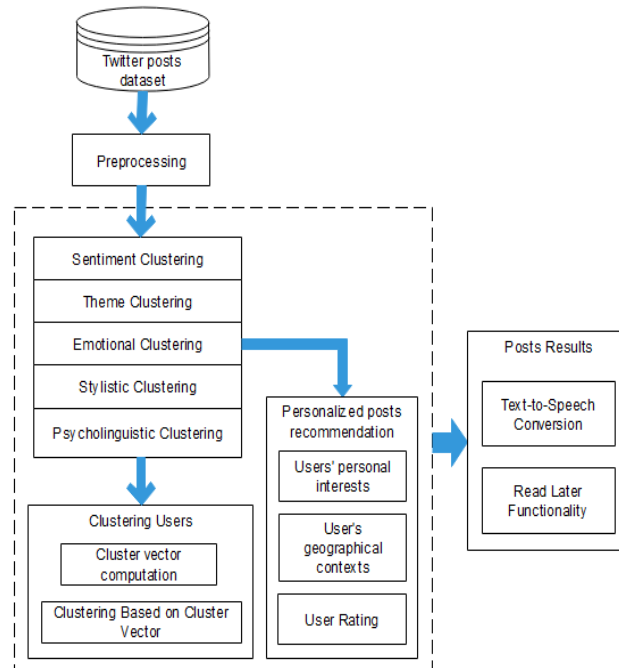

Fig. 1 Proposed System Architecture

Advantages of Proposed System:

- The approach is independent of the pre-existing social relations for members within a group and the approach considers behavioral similarity between the users in terms of their response pattern towards different aspects.
- The approach proves to be beneficial in tackling cold start problem, i.e. the cases where a new post has not been rated yet.
- Like minded members within a group are obtained by considering similarities in various dimensions.
- The first work is based on recommending posts relevant to a user based on interests expressed by them to the content of the posts, within a social network group and also one that helps in identifying members aimed at spreading unpopular posts within a group.
- The system is beneficial for users to listen the posts.
- The system also provides read later posts functionality to the users.
- The system also provides rating to the user based on the posts clustering.

## 5. MATHEMATICAL MODEL

### 1. Clustering Based On Cluster Vector:

To check the validity of the similar users formed from initial clusters, the members within a cluster are made to undergo similarity check. This is to check the confidence values of the users. It is measured using Pearson's correlation coefficient, which can be computed as follows:

$$sim_{m,n} = \frac{\sum_{p \in P} (r_{mp} - r'_m)(r_{np} - r'_n)}{\sqrt{\sum_{p \in P} (r_{mp} - r'_m)^2} \sqrt{\sum_{p \in P} (r_{np} - r'_n)^2}} \quad (1)$$

Where m and n are users whose similarity is to be identified. P refers to the set of posts which are liked or shared by at least one of them.  $r_{mp}$  refers to the posts liked by m and  $r'_m$  refers to the average rating of user m.

## 2. Group Policy Management:

Acceptability:

This term is defined in association with the posts. A post is checked for its acceptability with respect to how the different aspects (sentimental, psycholinguistic, stylistic, emotional and thematic) of the post are liked by the members of the community. It shows an aspect based score.

$$Acceptability(p) = \sum_M \sum_{i \in clus} val(C_{mi}) \quad (2)$$

Where, *clus* is a list that stores the cluster of the post *p* with respect to different aspects.  $val(C_{mi})$  gives the vector values (0 or 1) associated with the cluster vector of member *m* with respect to the aspect *i*.

Popularity: The term popularity is defined for both posts and members within a community.

$$popularity(p) = Acceptability(p) + share(p) + (com_{pos} + likes_{pos}) + \overline{com}(p) + \overline{likes}_{com} \quad (3)$$

Where  $share(p)$  is the number of shares for the post *p*,  $com_{pos}$  is the number of positive comments for *p*,  $likes_{pos}$  is the like obtained for positive comments,  $\overline{com}$  is the number of negative comments for *p* and  $\overline{likes}_{com}$  is the negative comments obtained for *p*.

## 6. CONCLUSION

The paper discusses a novel solution for the least addressed problem of clutter created out of group messages in online social networking sites. The method follows a different approach by considering linguistic features of data that are readily available from a social networking group. It does not depend on any of the pre-existing social relations between users unlike customary methods. The method shows a considerable degree of accuracy in predicting the response of a member to a post. The methodology proves to be an efficient means for managing group policies by providing a trusty environment. It offers a means to provide notification to group admin regarding activities of members within a community whose posting patterns do not suit the group principle.
