

# Stock Price Prediction Using Long-short Term Memory

**Prof. Neha Patidar**

Assistant Professor, Institute of Management Studies, Noida

## Abstract

The prediction of stock value is a complex task which needs a robust algorithm background in order to compute the longer term share prices. Stock prices are correlated within the nature of market; hence it will be difficult to predict the costs. The proposed algorithm using the market data to predict the share price using machine learning techniques like recurrent neural network named as Long Short Term Memory, in that process weights are corrected for each data points using stochastic gradient descent. This system will provide accurate outcomes in comparison to currently available stock price predictor algorithms. The network is trained and evaluated with various sizes of input data to urge the graphical outcomes.

**Keywords:** Machine Learning, Stock Price Prediction, Long Short- Term Memory, Stock Market, Artificial neural Networks, National Stock Exchange

## 1. Introduction:

The share market is a place where the shares of a public company are traded. As discussed in [7] the volatile nature of the stock market makes it an area which needs an abundance of analysis with the old data predicated. The previous stock trend prediction algorithms use the historic time series stock data. the typical scientific stock price forecasting procedures are focused on the statistical analysis of stock data. In the paper will develop a stock data predictor program that uses previous stock prices and data will be treated as training sets for the program to predict the stock prices of a particular share this program develops a procedure.

This model considers the historical equity share price of a company price and applies RNN (Recurrent) technique called Long Short Term Memory (LSTM). The proposed approach considers available historic data of a share and it provides prediction on a particular feature. The features of shares are Opening price, day High, day Low, previous day o price, Close price, Date of trading, Total Trade Quantity and Turnover. The proposed model uses the time series analysis in order to predict a share price for a required time span. the proposed will be considering Indian stock exchange Company named as The National Stock Exchange of India Limited (NSE). The National Stock Exchange (NSE) is the Indian stock exchange entity, the NSE was the first exchange in India to provide a modern, provides latest facility to the investors spread across the length and breadth of the country. It has thoroughly modern with all latest facilities, , which provides investors with the facility to trade from anywhere in India. This has a decisive role in reforming the Indian equity market to add increased transparency, convergence and efficiency to the capital market. NSE's Common Index, The CNX NIFTY, is used prodigiously by the investor across India as well as globally. It provides accommodation for the exchange, settlement and clearing in equity and debt market and additionally in derivatives. This is one of India's most astronomically enormous mazuma, currency and index options trading exchanges worldwide. There are numerous domestic and ecumenical companies which have an interest in the exchange. Several regional companies include TATA, WIPRO, HDFC and YES BANK Ltd. Among

pilgrim investors, few are strategic holdings of the city party, Mauritius limited, Tiger Ecumenical five holdings.

As suggested by [3] The Long Short Term Memory (LSTM) networks are a type of recurrent neural network (RNN) capable of addressing linear problems. LSTM is a deep learning technique. Long-term Memory (LSTM) Units are enforced to learn very long sequences. This is a more general version of the gated recurrent system. LSTM is more benign than other deep learning methods like RNN or traditional feed forward because LSTMs tackle the evanescent gradient issue possessed by [10].

Paper is ordered as follows. In Section II, related works are discussed. Section III represents the proposed system used and Section IV represents the proposed algorithm. In Section V the results are presented and conclusions are drawn in Section VI.

## 2. Related work:

While doing the literature survey, the data about Stock market prediction systems that are as of now being utilized are considered.

Over the most recent two decades determining of stock returns has become a significant field of research. In the majority of the cases the scientists had endeavored to build up a straight connection between the information macroeconomic factors what's more, the stock returns, be that as it may, with the revelation of non linear slants in the financial exchange record returns, there has been an incredible move in the focal point of the scientists towards the nonlinear expectation of the stock returns. Despite the fact that, there after numerous writing have come up in nonlinear measurable displaying of the stock returns, the majority of them required that the nonlinear model be indicated before the estimation is done. in any case, for the explanation that the financial exchange returns being boisterous, unsure, confused and nonlinear in nature. There are various functions used to forecast the parameters. Mainly include, binary threshold, linear threshold, hyperbolic sigmoid, and brown.

The Investigation of Stock Market Prediction Using Machine Learning Approach has been mentioned. The stock exchange forecast has become a sharp area of interest. Particular assessment is one of them, yet it does not reliably deliver specific results, so it is essential to develop strategies for progressively accurate gauge. All the procedures recorded under the backslide have their own ideal conditions and obstacles over their various accomplices. The way in which straight backslide models act is that they are consistently fitted using the least squares approach, however they may be fitted in different habits, for example by reducing the "non-appearance of fit" in some other standard, or by diminishing a disabled variation of the least squares setback work. Again, the least squares approach can be used to fit nonlinear models.

The impact of the financial ratios and technical analysis on stock price forecasting using random forests, The use of AI and human-made awareness frameworks to predict stock costs is a growing example. A constantly increasing number of experts spend their time every day considering ways to deal with techniques that can further improve the precision of the stock conjecture model. As a result of the galactic number of decisions available, there can be n number of ways on the most capable strategy to envision the expense of the stock, anyway all techniques don't work a comparable way. The yield changes for each methodology whether or not comparative educational file is being applied. In the alluded to paper the stock worth gauge has been finished by utilizing the self-confident timberland figuring is being used to betoken the expense of the stock utilizing fiscal extents structure the perspective quarter. This is just a single technique for optically crusading the circumstance by advancing toward it utilizing an insightful model, utilizing the capricious boondocks to anticipate the future expense of the stock from recorded data. However, there are continuously different components that influence the cost of the stock, such as the suspicions of the money-related authority, the general assessment of the association, news from sundry outlets, and even events that cause the entire trade protection to change, by using the cash related size in the vicinity of a model that can strongly separate assumptions, the accuracy of the stock value forecast model can be extended.

It is also mentioned in [1] that stock value Prediction by methods for Multi-Source multiple instance learning unequivocally foreseeing the protections trade is a troublesome task, anyway the web has wind up being a useful gadget in making this task less difficult, due to the related course of action of the data, it is certainly not difficult to evacuate certain inclinations right now, it is less difficult to establish associations between different variables and, for the most part, a case of adventure The way in which budgetary trade information can be adequately predicted is through the use of some different options from specific legitimate data and the use of different strategies, such as the use of a feeling analyzer, to suggest a remarkable relationship between the emotions of individuals and how they are influenced by the enthusiasm for express stocks. One of the progressively noteworthy areas of the desire strategy was to extract huge events from web news to see how they had an impact on stock costs. It is also

mentioned that trade prediction protection: using historic data analysis. The stock or offer expense can be foreseen using chronicled data and its example in all actuality there is need to apply counts to anticipate the expenses. The customary frameworks are just worried about variety of an element that is selected for forecast. The latter is usually achieved with the benefit of the Genetic Algorithms (GA) or the Artificial Neural Networks (ANN's)[5], but they neglect to establish a relationship between their stock costs as long-distance fleeting dependencies.

RautSushrut et al.[2] suggested that supervised learning classifier be used to forecast stock price movement based on financial index data, and determine their ability. In the financial market computational analytical approaches have been portfolio modeling. A discussion about the statistical AI methodology has been addressed; the usage of SVM methodology has been shown in the paper and also shown that tactical methodologies can be applied to predict the stock prices.

Manoj S Hegde et al.[3] investigated that The Long Short Term Memory (LSTM) networks are a type of recurrent neural network (RNN) capable of solving in volute linear problems, and also there is a discussion about the usage of RNN (Recurrent Neural Networks ) to predict the share prices.

M. Roondiwala et al.[4] proposed that the Long Short-Term Memory is the most popular RNN architecture. In the secret network layer, LSTM introduces a memory cell; a processing device that replaces conventional artificial neurons, using these memory cells, networks can effectively link memory and remote input in time, making it suitable to dynamically capture data structure over time with a high predictive limit. It is also shown in the paper that the stock prediction can be done on the NIFTY50 shares. The data collection is one of the major step and later the training of our model and there is a need to test the algorithm by applying different data set to the algorithm. Our procedure will be discussed in coming sections

As Kim and H. Y. Kim et al.[5] identified that another significant issue with basic ANNs for stock forecast is the marvel of detonating fleeting inclination, where the loads of a gigantically huge system either become excessively massively enormous or too inuscule (respectively), drastically easing back their union to the ideal worth. This is regularly brought about by two components: loads are instated self-assertively and the loads progressively proximate to the end of the system moreover slope to transmute significantly more than those at the beginning. It is also mentioned in the paper that the usage of LSTM networks can be applied in procedure of predicting share prices.

As discussed by S. Selvin et al.[6], Customary types for dealing with the financial exchange investigation and the stock-value forecast include a major review of the past stock-exhibition gander and the general credibility of the organization itself, and a measurable investigation that is solely concerned with the calculation and recognition of stock-value designs, it also mentioned in the paper that different types of analysis that can be performed in order to predict the stock value.

Loke.K.S et al.[7] suggested that the volatile nature of the stock market is an area that needs a lot of analysis based on historical data. Traditional stock trend forecast algorithms use historical time series stock data, traditional technical forecasting procedures for stock prices are based on statistical data analysis. in the paper author also talks about the change and advancements in the process of predicting stock prices using AI and Machine Learning methodologies, there are many research which are being conducted to find a accurate model to predict the stock prices and there is no universal solution which is available to apply, hence the historic data of a share will be considered for stock price prediction.

Xi Zhang<sup>1</sup> et al. [8] suggested that the stock markets play critical roles in modern society's economic operations. It is also metioned in the paper that the analysis can be performed an the data that is retrieved from a legitimate source and proposed a methodology in which we can utilize multiple source of information to predict the stock values.

Tao Xing and Yuan Sun et al. [9] suggested a model which considers the historical equity share price of acompany price and applies RNN (Recurrent) technique called Long Short Term Memory (LSTM). The proposed approach considers available historical data of a share and it applies prediction on a particular feature. The features of shares are Opening price, day High, day Low, previous day o price, Close price, Date of trading. The proposed model uses the time series analysis in order to predict a share price for a required time span.

Jordan Prosky et al. [10] suggested that, the CNN methodologies and its usage in predicting stock prices, a method to apply sentiment analysis on stock prediction.

As mentioned by X. Shao and D. Ma [11] it is a more general version of the gated recurrent system. LSTM is more benign than other deep learning methods like RNN or traditional feed forward neural networks because LSTMs

tackle the evanescent gradient issue possessed by RNNs and it is also mentioned that how to implement LSTM along with K-means algorithms for a short term stock predictor systems.

### 3. Proposed System:

As represented in the previous section getting the historical data from market is mandatory step. Then there is a need to extract the feature which is required for data analysis, then divide it as testing and training data, training the algorithm to predict the price and the final step it to visualize the data. Fig. 1 represents the Architecture of the proposed system.

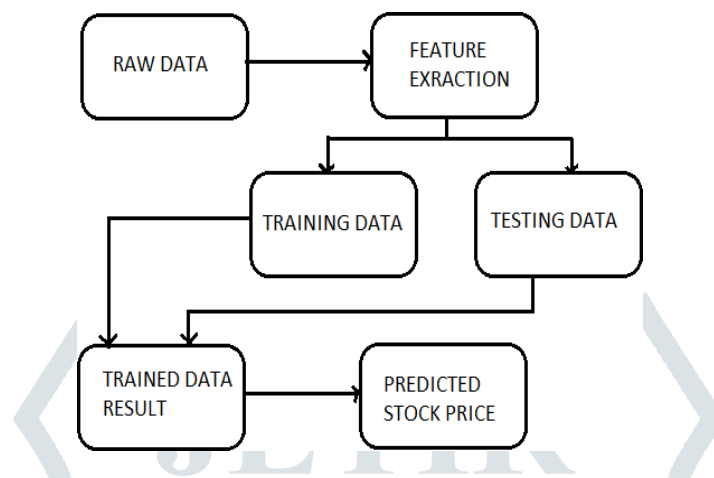

Figure 1: System Architecture

The typical LSTM unit consists of a cell, an info door, an entrance door and a door with a view. The cell collects values over discretionary time intervals, and the three inputs manage the progress of data into and out of the cell. The main advantage of the LSTM is its ability to learn context-specific temporal dependence. Each LSTM unit collects information for either a long or short period of time (hence the name) without explicitly using the activation function within the recurrent components. A significant certainty to note is that any cell state is uniquely increased by the output of the overlooked entryway, which changes somewhere in the range of 0 and 1. In other words, the overhead door in the LSTM cell is responsible for both the loads and the capacity to initiate the cell state. Subsequently, data from a past cell state can pass through a cell unaltered rather than expanding or decreasing exponentially at each time-step or layer, and loads can meet their ideal quality in a reasonable measure of time. This allows LSTM's to take care of the evaporating slope issue – as the value put away in the memory cell is not iteratively adjusted, The inclination does not disappear when prepared with back engendering, where markets such as NSE and BSE are considered to be Indian trading entities for our analyzes.

3.1. Parameters used List of parameters/Symbols used in this paper is listed in Table 1

Parameter Used	Meaning
Date	Date of stock price
Open	Open price of a share
Close	Closing price of a share
Volume/Trade Quantity	Number of shares traded
High	Highest share value for the day
Low	Lowest share value for the day
Turnover	Total Turnover of the share

### 4. A Stock Price Predictor Using LSTM:

The proposed framework that learns online anticipating the close costs of the stock with the assistance of Long Short Term Memory (LSTM). The Long Short Term Memory (LSTM) is a counterfeit intermittent neural system (RNN) design[1] used in the field of deep learning, Unlike standard feed forward neural systems, LSTM has input associations. Not only does the procedure not focus on single information (e.g. pictures) but also on full information arrangements, (For example, a speech or a video). For example, LSTM is material for undertakings, such as un

partitioned, associated penmanship recognition, speech recognition and recognition of peculiarities in arranged traffic or IDS (interruption location frameworks).

### Algorithm 1: Stock prediction using LSTM

**Input:** Historic stock data

**Output:** prediction of stock price using price variation

Step 1: Start.

Step 2: Data Preprocessing after getting the historic data from the market for a particular share.

Step 3: import the dataset to the data structure and read the open price.

Step 4: do a feature scaling on the data so that the data values will vary from 0 and 1.

Step 5: Creating a data structure with 60 timestamps and 1 output.

Step 6: Building the RNN (Recurrent neural network) for Step 5 data set and Initialize the RNN by using sequential repressor.

Step 7: Adding the first LSTM layer and some Dropout regularization for removing unwanted values.

Step 8: Adding the output layer.

Step 9: Compiling the RNN by adding adam optimization and the loss as mean\_squared\_error.

Step 10: Making the predictions and visualizing the results using plotting techniques.

Before processing the data there is a important step that is to collect the information from market. Information assortment is the principle step in our proposed framework importing of the information from advertise clearing organizations like BSE (Bombay Stock Exchange) and NSE (National Stock Exchange). The dataset that will be utilized in the market expectation must be utilized to be separated dependent on different perspectives. Information assortment additionally supplements to upgrade the dataset by including more information that is outside. Our information for the most part comprises of the earlier year stock costs. For python available packages for retrieving the data from NSE is NSEpy The next step is to preprocess the data; in this step the Information Pre-Processing is a significant advance in information mining here the change in crude information into a basic configuration is required. The information which is retrieved from source will be conflicting, fragmented and it will contain mistakes. The preprocessing step will purify the information; toward the end there is a need to perform highlights scaling which will restrict the factors. The preparation of the model incorporates crossapproval, which is a very well-founded, projected execution of the model using the preparation information. the purpose of the tuning models is to explicitly tune the calculation training is to add information to the calculation itself. The test sets are immaculate, as a model ought not to be made a decision about dependent on concealed information. Scale up the information to the genuine offer costs. The final step is to draw the data using visualization technique that helps to show the variation of data in the outcome of our algorithm.

## 5. Results and Discussion:

The implementation of proposed LSTM model using python which predicts the future price of TATAMOTORS share based on its historical data. The below visualization figure shows the visualization of TATASHARE prediction. In our paper the implementation of an algorithm which predicts the stock price of a share for given period of time, the below graph from our algorithm will show the predicted price of TATAMOTORS share. In the result shown in the below graph is the plotted form our algorithm outcome by applying 96 LSTM units for achieving the accuracy. The Fig 2 is drawn from original dataset and also shown the result by comparing its correctness with the trained model from algorithm that is defined in the previous section. the “x” axis is share price. The “y” axis is days. The data is slot of 1500 days is shown in the Fig 3.

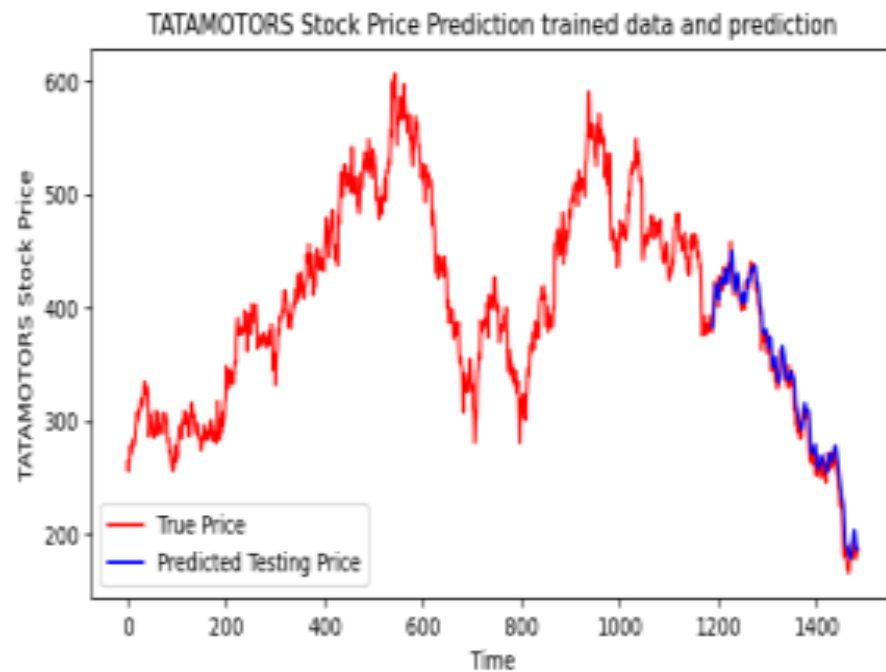

Figure 2: predicted testing stock price

The Fig 3 is drawn from original dataset also shown the result by comparing its correctness with the trained model from algorithm which that is defined in the previous section. the “x” axis is share price. The “y” axis is days. The data is slot of 300 days is shown in the Fig 3.

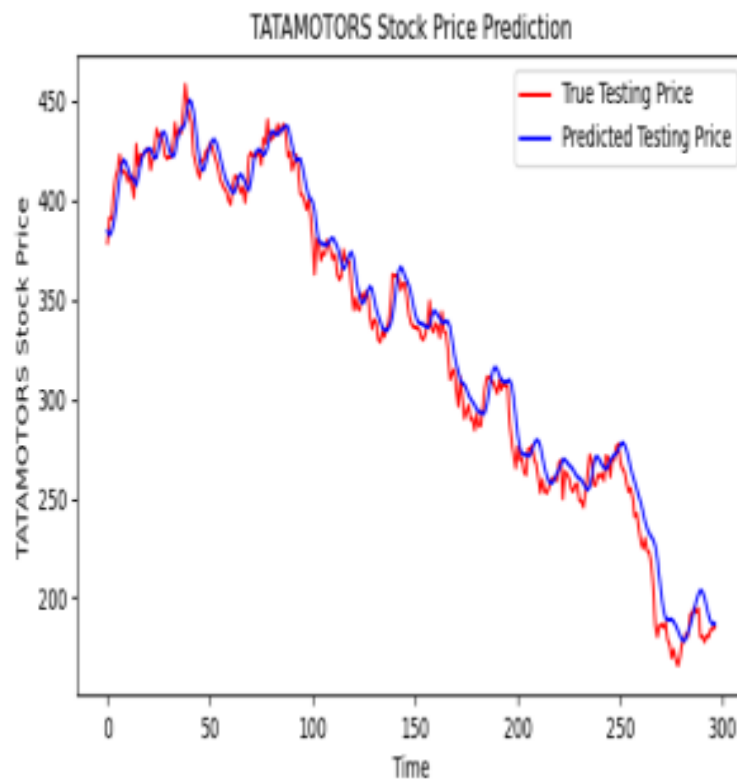

Figure 3: predicted stock price

In the Fig 2, the graph has been plot for whole data set along with some part of trained data. The graph is showing the open price of TATAMOTORS share for 1484th day's opening price with very minimal loss. the algorithm has plotted the graph successfully along with the predicted price testing price (blue) and true price (red), there is a slight difference in predicting the price between the predicted price testing price (blue) and true price (red), which proves that our algorithm is able to predict the with minimum loss rate for the given complete data set of a particular share.

In the Fig 3, the graph is showing the open price of TATAMOTORS share for 300th day's opening price with very minimal loss. the algorithm has plotted the graph successfully along with the predicted price testing price (blue) and actual testing price (red), there is a slight difference in predicting the price between the predicted price testing price (blue) and actual testing price (red), which proves that our algorithm is able to predict the with minimum loss rate of 0.0024. The proposed algorithm is able to predict the share price with very low loss and error rate, if increase the epoch batch rates the training will be more efficient, in the above section we have used epoch batch size of 50 to predict the stock prices. The figure shown in the previous section (fig 2 and fig 3) of the proposed algorithm is able to predict the price, with loss: 0.0024 300th days open price was 172 rupees INR and our predicted price is 166 rupees per share.

## 6. Conclusion:

The study of the share is carried out in this paper and it can be carried out for several shares in the future. Prediction could be more reliable if the model trains a greater number of data sets using higher computing capacities, an increased number of layers, and LSTM modules. In future enhancement the inclusion of sentiment analysis from social media to understand what the market thinks about the price variation for a particular share and it can be implement this by adding twitter and Facebook API to our program as Facebook is a leading social media which has lots of market trend information posted by users.
