Abstract : The current research considers the spatio-temporal change in the cropping patterns of the Erandol taluka, Jalgaon district, Maharashtra, between the years 2018-19 to 2025-26 based on the secondary agricultural statistics and graphical analysis. To evaluate the structural changes and seasonality, data on crop-wise sown area was classified into food grains, oilseeds and cash crops. The findings indicate very dynamic and season-based cropping, with strong inter- annual shifts between food grain and cash crop dominance. The structurally important crops are the cash crops especially cotton and the foodgrains increase or decrease as a result of variability of rainfall, availability of irrigation and market demand. Oilseeds take perpetually a secondary position meaning that it is not diversified. The paper outlines the susceptibility of the current cropping pattern to both climatic and economic stresses and provides the rationale behind planning of crops and the role of better irrigation systems and diversification efforts. The results are resourceful in terms of taluka-level agricultural planning and policy interventions to increase semi-arid region sustainability and resilience.

Keywords:

Cropping pattern, Spatio-temporal analysis, Agricultural land use, Monsoon variability, Irrigation dynamics.

Introduction:

Agriculture comprises an important and basic economy of the Indian economy, which provides the backbone of food security, rural livelihoods, and industrialization. It makes use of a large percentage of the population and generates a lot of national income besides being sources of raw materials to the agro based industries like textiles, sugar and food processing. The presence of varied agro- climatic regions across India allows the production of a great variety of crops on an annual-round basis, with the major annual-round cropping seasons being Kharif, Rabi and Zaid. Even though agriculture in India is highly reliant on the southwest monsoon the rainfall susceptibility in most areas has been alleviated with the increase in irrigation infrastructure, such as canals, tube wells and modern micro-irrigation systems. Small and marginal farmers form the largest part of the sector and they apply both the traditional production methods and the modern inputs which includes high-yielding varieties, fertilisers, mechanisation and improved farming methods. However, structural and environmental issues, such as divided landholding, decreasing soil fertility, water scarcity, climate-change effects, price fluctuations, and low agricultural incomes still affect Indian agriculture. All these concerns are why sustainable practices, technological innovation, and favourable policy interventions are needed. It is a measure of the relative distribution of the area to various crops and distribution of these crops on the basis of the crop cycles like Kharif, Rabi and Zaid. Climatic conditions, rainfall, soil type, availability of irrigation, available agricultural technology and market demand are those factors that determine the cropping pattern of a region. To achieve increased productivity, reduce risk and to maintain soil fertility, farmers are resorting to mixing, multiple and crop rotation. An organized arrangement of the crop pattern ensures efficient use of land and water, food security and increases the income of the farmers.

Study Area:

Erandol is a local government and a sub-district in Maharashtra, Jalgaon district, India. The Coordinate extend of taluka is approximately $20^{\circ} 55' N$ and $21^{\circ} 05' N$ and $75^{\circ} 15' E$ and $75^{\circ} 40' E$. It is located in the north-western portion of the state, and is included in the Khandesh region. The town is located on the banks of the Anjani River an affluent of the Tapi, about forty kilometres to the southwest of the administrative nucleus of the district, Jalgaon city. The agricultural activities at Erandol taluka resemble the traditional mode of cropping that is found in the north Maharashtra region due to the presence of black soil, semi-arid climate and accessibility of irrigation facilities within the area. The majority of crop portfolios during the monsoon (Kharif) season include sorghum (jowar), pearl millet (bajra), cotton, a combination of pulses, and oilseeds, since these species are strong in rain-fed agriculture, and they do not demand too much water. The use of cotton, especially, makes it one of the most important cash crops, which can be explained by the fertility of black soil and the market demand. During the post-monsoon (Rabi) season, wheat, gram (chickpea) and various pulses are grown and they cash in on the available soil moisture. In addition, horticultural and vegetable crops such as onion, chilli, banana and other vegetables form a significant percentage of crop combination in regions that have access to irrigation sources and mostly where wells are located or close to the canal system. The agricultural schema therefore incorporates cereals, legumes, cash crops and vegetables hence absorbing the conventional agronomic habits; it is at the same time responsive to the needs of the market.

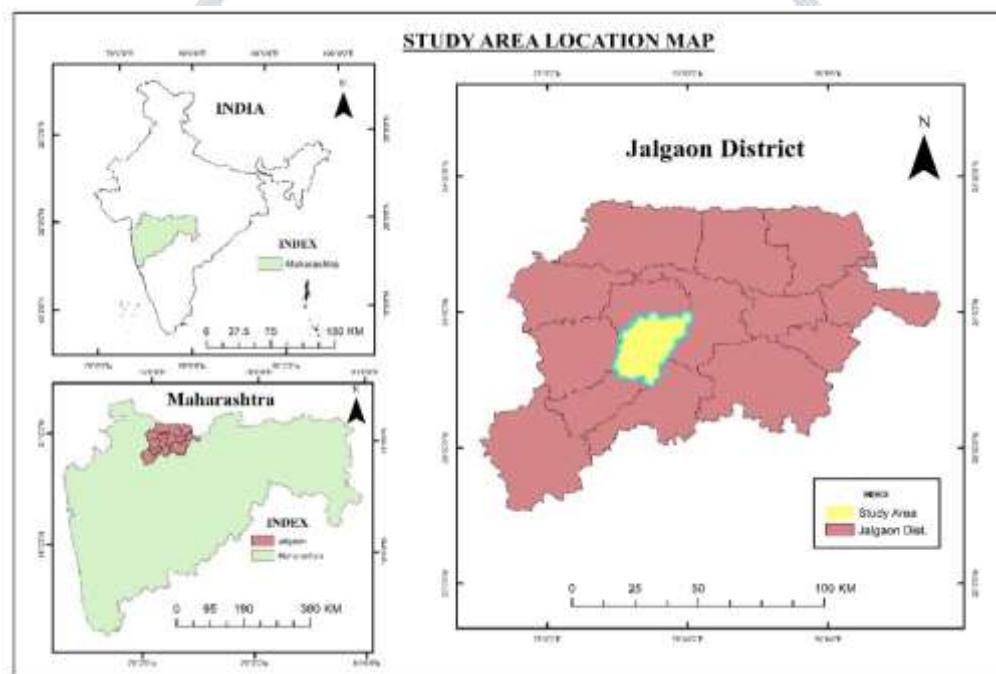

Fig. no. 1: Location map of study area

Methodology:

The present study analyses the cropping pattern of Erandol taluka for the agricultural year 2018–19 to 2025-26 using secondary agricultural statistical data. Crop-wise sowing area data were collected from Taluka Agricultural Officer, Erandol and district statistical handbooks. The crop sowing data separated in 3 seasons Kharif, Rabbi and Zaid for analysis. Then crops divided into three types Foodgrains, Oilseeds, Cash Crops. In foodgrains crops included Jowar, Bajra, Mazie, Wheat, Tur, Moong, Urad, Gram, other cereals and pulses. In Oilseeds crops included Sesame, Soyabean, Groundnut, Sunflower and other oilseeds. In Cash crops included Sugarcane and Cotton. The total sown area under each category was calculated and expressed as a percentage of the gross cropped area to understand their relative dominance. These proportional values were visually represented using a pie diagram in Microsoft excel, which facilitates easy comparison of crop categories and highlights the prevailing cropping structure.

Fig. no. 2: Methodology flowchart

Interpretation:

Conspicuous changes in the structure of agricultural production of Erandol taluka over years 2018-19 to 2025-26, particularly the proportionate share of foodgrains, oilseeds, and cash crops are illustrated by year-by-year pie charts in based on crop statistics on Excel.

Fig. no. 3: Pie-chart 2018-19

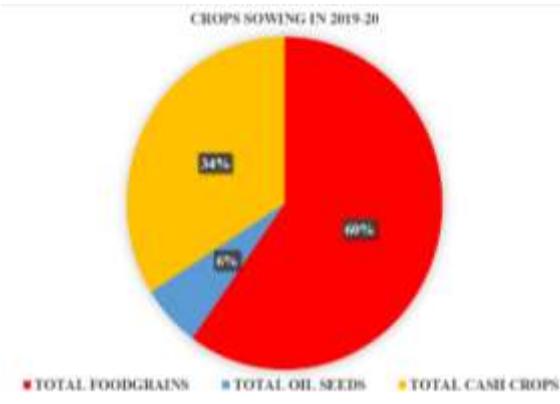

Fig. no. 4: Pie-chart 2019-20

As per **table no.1** in the 2018-19 season, the agricultural environment was dominated by cash crops, which constituted 61 per cent of total sown area, surpassing the foodgrains (34%) and oilseeds

(5%). This finding is consistent with the Excel data set which reveals that there was a large area of cotton which way exceeded the combined total of area devoted to food grains.

As per above **table no.2** severe change in structure can be seen in 2019-20, where the share of foodgrains is increasing rapidly by a factor of about 60 percent accompanied by a fall in cash crops to 34 percent and oil seeds is kept on the margins at 6 percent. The trend is indicative of a short-term shift to foodgrain-based production, which is perhaps due to the fluctuation in precipitation, market price changes, or an increase in risk aversion by the agrarian stakeholders.

Fig. no. 5: Pie-chart 2020-21

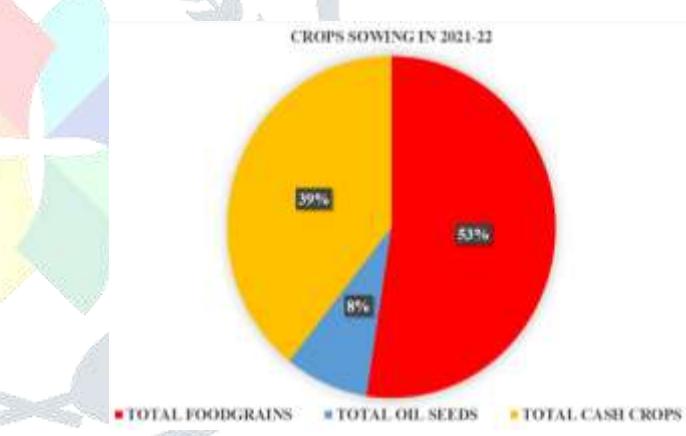

Fig. no. 6: Pie-chart 2021-22

The cropping structure in the successive crop years of 2020- 21 and 2021- 22 can be discerned through **table no.3 and table no.4** is relatively balanced, with food grains continuing to play a dominant role of approximately 53%, cash crops playing a smaller role at 39%, and oilseeds playing a minor role at 8%. This period denotes moderate diversification that is supported by the rabi growth of cereals and pulses which have been recorded in the excel entries.

Fig. no. 7: Pie-chart 2022-23

Fig. no. 8: Pie-chart 2023-24

As per **table no.5** 2022-23, the cash crop share turns back to 45% and becomes nearly equal to that of food grains at 48% suggesting a revival of market-oriented crop focus. This trend continues to 2023-24 which can be observed through **table no.6**, with the cash crops increasing further to 47%, foodgrains remaining more or less at 49% and oilseeds going down to 4%.

From the above **table no.6**, the cash crops dominate once again in the 2024-25 cycle (50%), ahead of foodgrains (45%) and this indicates a re-occurrence of commercial agriculture. However, the next 2025-26 year indicates a sharp change of foodgrains growth to 62% with a reduction of cash crop to 34 to oilseeds remaining low at 4% can be seen in **table no.7**.

Fig. no. 9: Pie-chart 2024-25

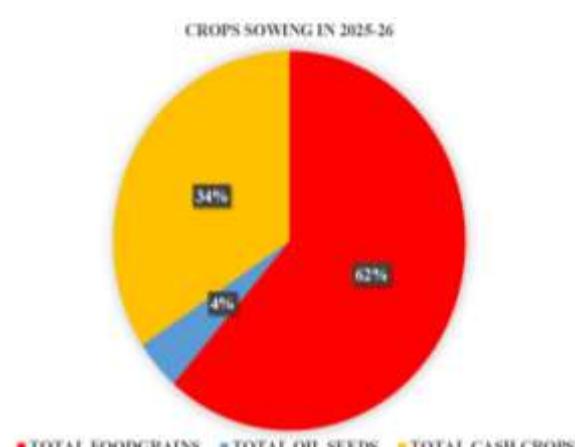

Fig. no. 10: Pie-chart 2025-26

Taken together, the visual and spreadsheet data synthesis proves that, although cotton-oriented cash cropping still does not lose its structural importance, the agricultural structure of the Erandol taluka is highly dynamic, which is manifested in significant yearly fluctuations in the prevalence of foodgrain and cash crop. There is an unstable position of oilseeds (4-8%), which highlights a

reserved diversification despite the policy requirements. Such oscillations underline the fact that the system is sensitive to monsoon variability, access to irrigation, and market dynamics and therefore highlights the need to ensure balanced and resilient crop planning.

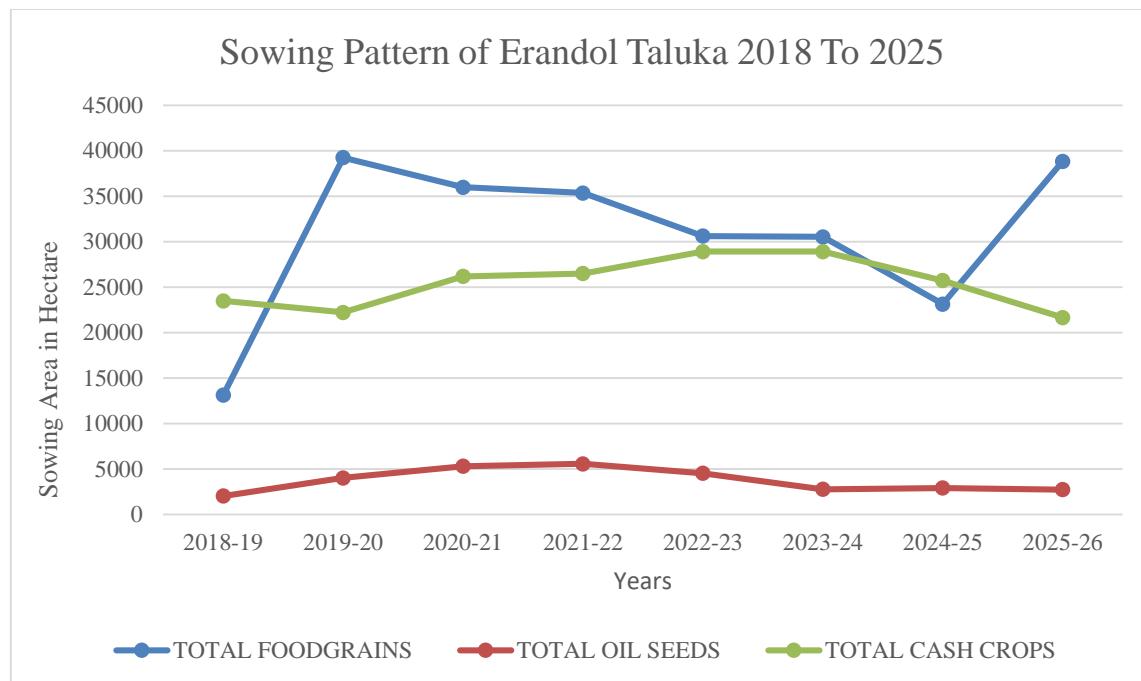

Fig. no. 11: Line Graph 2018-25

The Fig. no. 11: Line Graph shows that the total area of foodgrains sown has a considerable range with a sharp increase in 2018-19 to approximately 39000 ha in 2019-20, after which there is a slow decrease to 2024-25 and a sharp increase again in 2025-26. These oscillations indicate high sensitivity of foodgrain cultivation to variations of monsoon, availability of rabi irrigation and policy or price signals. Cash crops on the other hand represent comparatively moderate but steady variation, staying within the band of 22,000-29,000 ha through most years, which implies structural stability of commercial growing, specifically cotton. The oilseeds are the most stable and at the lower end of the study period with a range of about 2000 to 5500 ha indicating low preference by the farmers in spite of their agronomic value.

Results and Discussion:

The findings indicate the existence of a very dynamic and climate responsive cropping regime in Erandol taluka between the year 2018-19 and 2025-26. The considerable inter-annual changes in the foodgrain pre-eminence to the cash crop dominance and the reverse are evidence that the farmers are constantly changing their crop preferences with regards to monsoon variability and irrigation availability, market prices and perception of risk. Despite its structural significance, cotton-based cash cropping is occasionally minimized in years when the foodgrains grow implying the adaptive risk management in the years when there is uncertainty of rainfall. The reason why kharif prevails and zaid is hardly cultivated is due to the reliance on the monsoon-based rain and low use of the potential of summer irrigation. Although there has been moderate growth in rabi cultivation in some years, irrigation limits and reliance on ground water limits multi-season cultivation. The low proportion of oilseeds (4-8) is always a sign of a low diversification which could be attributed to the uncertainty concerning the yields, the lack of access to the market and relatively low profitability. The observed changes also suggest that the pattern that is being observed in the cropping is not moving towards a stable diversified system, but instead is swinging between subsistence-oriented and commercial orientations. This instability enhances susceptibility to climatic extremes and price fluctuations, which may have an impact on sustainability of income of farmers and regional food security.

Conclusion:

The current research paper establishes that the Erandol taluka in terms of its cropping pattern in the years 2018-19 to 2025-26, is very dynamic, monsoon-based and dominated by cash crops more especially cotton. Even though foodgrains are periodically growing and even exceeding cash crop in some years, the changes are mostly short-term and influenced by the fluctuation of rainfall, the presence of

irrigation, and the market. Oilseeds always hold a secondary position, which means that the crops are not diversified despite the agronomical and economic significance of the crops. The overall examination of statistical information and graphical data provides an understanding that the system of crop is not stable in its structure over time and still is susceptible to climatic unpredictability and price changes. To enhance sustainability, it is necessary to strengthen the irrigation infrastructure, facilitate diversified and climate-adaptive agricultural decisions, and incorporate geospatial instruments to monitor agriculture
